AT BUTTE.—Inter-Mountain, May 2: The Anaconda and St. Lawrence mines yet remain in a state of partial suspension. The water continues to be poured into the shaft of the latter, and the thousands of men who found employment at these works are either parading the streets with those already out of employment or else gone to other parts in search of work. These men being thrown out of employment causes much hardship, and hope is expressed by both those who are now employed and unemployed that the differences existing between the two great corporations may soon reach an amicable adjustment. The mines thus far are giving employment to but a few men, and they are only doing such work as is necessary for the care and preservation of the property. The mines that have thus temporarily suspended are the Mountain Con., Jim, High Ore, Green Mountain, Anaconda, Modoc and St. Lawrence, mines giving employment to about 1500 miners underground, besides the number who find employment in an indirect way on the surface. In most of them at present sinking is in progress and will continue during the fall or until another road is completed into the town of Anaconda. Reports have been in circulation during the past, and the information has emanated from quite a reliable source, that work would be resumed on or about the 15th of this month, and from the activity in the yards of the Montana Union, it would lead one to believe the time to be not far distant. The Boston & Montana from the first day has increased its output under the capable and careful management of Superintendent Couch. Improvements have been started by some of the larger properties, showing a disposition to keep step with the times. The Parrot Company has commenced the erection of a large and commodious hoist that is now nearing completion and is an ornament to the town and camp. It entirely engulfs the old one, which was in itself a good-sized building. The foundation or bed for the large engine is being put in position. This massive piece of machinery, when once in position, will be the largest in the camp with no single exception. The next in size will be the large one about to be put up on the Leonard shaft in Meaderville. Both engines will be here just as soon as they are completed. The Parrot engine is now near to completion, while the Leonard engine, a more delicate creation but as powerful, may not be here for a few months. All the mines and mills on the bill are again in full blast. The Alice is running entirely on her own ore, while the Lexington, though doing some custom work, depends mostly on its own output. The Moulton has resumed the working of custom ore and again the mill is running continually. This mine, when once the shaft is down, will take its former place as one of the greatest producers in the district. In the Burlington country prospecting is again in vogue, and many of the leasers are hunting up prospects. The West Nettie changed hands and is now under an entirely different management. The boys are holding their own in a manner that is a credit to the mine. The Blue Bird is working a full complement of men, both in the mine and mill, and a quantity of ore is being taken out that promises well for the next dividends. This is one of the best managed mines in the camp. Some of its underground workings is timbered with square sets, while mostly stulls are used. The ground in this mine is very loose and can be handled only by practical and experienced miners. The mill is under the personal supervision of Mr. Monroe, and since he came into the superintendency of this property the bullion has become better than ever before. The miners of the Park canyon country have for the past week been bending their energies to discover what is on the surface, with the exception of the Homestake, which is satisfied in developing in depth and in which they are reaping their just reward. The Clinton Company persists in pushing through the mountain and is in already 700 feet. The tunnel is still being sent in as fast as men and money will allow. The ore is scattering, though the company has a strong ledge. Some very fine streaks of ore have been encountered, giving warrant that if depth is attained the future of the Park canyon country would be solved and a second Butte arise in that vicinity.

NEW MEXICO.

DEVELOPMENT WORK.—Silver City Enterprise, April 24: The International smelter folks have, about closed a deal for the delivering of 600 tons of second-class ore from the Bachelor mine at Volcano. The Mountain Key shipped 100 ounces of gold last week. The concentrates equal in value the free gold saved on the plates and the two together make a good weekly showing for a 15-stamp mill. A good

deal of work is being done at Chloride Flat in a quiet way. Joe Avey and the Jones brothers have a lease on the Flagler mine, from which they expect to extract a considerable amount of good ore. Tom Fox, of Stein's Pass has struck some very rich ore two miles south of the railroad. Two assays gave as a result 1121 ozs. silver and 1589 ozs. silver and \$160 gold per ton. Gibson & Johnson of Lordsburg have unearthed a bonanza west of Lee's Peak. The find consists of a deposit of heavy lead-silver ore and promises to pan out well. The ore is a heavy galena. Nat Bell, of the firm of Bell & Stephens, of Pinos Altos, went over to the Golden Rule mine on Tuesday. Mr. Bell has every confidence in the mine and believes it can be made to pay good profits. He will ship a lot of the ore to Pinos Altos for treatment by special process as the ore cannot be worked by amalgamation and hence the failure of the former operators of the mine. Charles Clair, of Shakespeare, who was in town Wednesday, informs the Enterprise that parties have recently visited his camp and bought a number of the old dumps, and are now shipping the ore to El Paso for reduction. He also states that sampling works will soon be erected at Lordsburg by Chicago parties. The machinery has already been ordered. Mr. Clair predicts that in six months the old camp of Shakespeare will be the best camp in Grant county. Add to the Bell & Stephens and Mountain Key gold shipments those of the Pacific Gold Co., the Aztec, Skillicorn & Snyder, and McDonald and company, and it will be found that Pinos Altos makes a better showing than any gold mining camp of its size in the United States. Four years ago these properties were all lying idle as are many other good properties to-day for lack of capital to furnish mills for the reduction of their ores. On the 20th of last month Messrs. Bell & Stephens brought down from Pinos Altos 65 pounds of melted gold in bars and again on last Monday 40 pounds more. This makes a good showing for the first month's installment on the proposed one ton gold brick for the world's fair. One hundred and five pounds per month will not quite fill the bill but the mill has not been running full time. Hereafter the shipments will probably be larger and the display at Chicago when the fair opens will be fully one ton weight of pure gold.

OREGON.

MINING SALE.—Bedrock Democrat, April 27: The necessary papers were yesterday executed, conveying a one-half interest in the Montana mine, situated in the Greenbush district to E. L. Groux of this city. The mine was discovered several years since by J. B. Hunsaker, who still retains the other one-half interest. Considerable development work has been done on the property. The vein is of a good milling grade and the ore is free milling, assaying \$7 in gold and \$167 in silver per ton. The consideration of the sale was \$2000.

PLACERS.—Chas. Blalock and J. E. Alexander are opening up extensive placer mines on Goose creek and so far their prospect is good.

The Mining Companies' Financial Standing.

The following is the financial standing on the first Monday of the present month of the mining companies listed on the two exchanges in this city:

ARIZONA MINES.		Cash.	Debt.
Challenger	\$ 6,181
Locomotive	1,519
Peer	241
Peerless	884
Silver King	143
Weldon	2,025
BODIE MINES—CALIFORNIA.			
Bodie Con.	19,296
Bulwer	9,901
Mono	5,430

MISCELLANEOUS MINES.			
Eureka Con.	13,169
Holmes	137,201

(A) With bullion to arrive and an assessment to be collected.
(B) Bullion on hand valued at \$51,757.18, with further shipments to arrive.
(C) Due on assessment No. 98, \$2440.50.
(D) On hand 18,355 ounces fine silver and further shipments to arrive as an offset.
(E) A sum of \$12,800 due from other companies as an offset.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING APRIL 28, 1891.

- 451,252.—CULTIVATOR—D. E. Barton, S. F.
- 451,253.—CULTIVATOR ATTACHMENT—D. E. Barton, S. F.
- 451,254.—CULTIVATOR BEAM—D. E. Barton, S. F.
- 451,255.—CULTIVATOR CLAMP—D. E. Barton, S. F.
- 451,256.—CULTIVATOR ATTACHMENT—D. E. Barton, S. F.
- 451,316.—PIPE—J. L. Cahalan, S. F.
- 451,317.—RECEIVER'S CASH BOX AND TRAY—B. F. Carman, S. F.
- 451,299.—MILK COOLER—W. W. Conder, Tillamook, Or.
- 451,319.—SASH HOLDER—G. A. Cooper, Alameda, Cal.
- 451,326.—TENSION AND CUT OUT FOR ELECTRIC RAILROAD—B. Jennings, San Jose, Cal.
- 451,199.—STONE SAWMILL—F. H. Kessler, S. F.
- 451,310.—DOCUMENT FILE—G. F. W. Schultze, S. F.
- 451,138.—SNOW FLOW—Small & Heintzelman, Sacramento, Cal.
- 451,314.—SNAP HOOK—Frank White, Pomona, Cal.

The following brief list by telegraph, for May 5, will appear more complete on receipt of mail files:

California—George F. Campbell, ladder; N. L. Darling, assignor to Benicia Agricultural Works, traction engine; J. J. Oraft, S. F., cable grip; A. Hartung, Nevada City, watch makers' jewel-setting cutter; A. C. Sewell, S. F., hatching machine; Collin Kondro Jr., Nevada City, valve gear for ore stamps; J. W. Lindsay, Fresno, horse-tail holder and rein guard; A. Sommer, Berkeley, neutralizing sulpho-chlorinated oil; L. A. Steger, San Jose, stratified brick; Anale T. Welch, San Jose, veterinary inhaler; James B. Williams, Oakland, insulated electric conductor.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SASH-HOLDER.—Geo. A. Cooper, Alameda, No. 451,319. Dated April 28, 1891. This is one of that class of sash-holds in which eccentrics or cams operate against the sashes to hold them. The object is to provide a simple and effective device adapted to operate on both sashes, automatic in its locking action, conveniently located, preventing any rattling of the sashes, and capable of being used as a right or left hand lock as may be desired.

RECEIVERS CASH-BOX AND TRAY.—B. F. Carman, S. F. No. 451,317. Dated April 28, 1891. This invention is especially intended for the use of those receivers to whom sums of money are passed at intervals—as for example, the receivers of carfare money, at whose offices the conductors successively repair for the purpose of turning over the money collected. The object of the invention is to provide an easy and perfectly safe receptacle for the transfer of the money from the person paying to the person receiving it, and at the same time to avoid all drafts usually occasioned by the opening of the passage through which the money is passed.

PIPE.—John L. Cabalan, S. F. No. 451,316. Dated April 28, 1891. This invention relates to that class of pipes formed and adapted to be laid in sections, making a continuous course, way, or conduit for any purpose—such, for example, as sewers, water-ways, ditches, gutters, etc. The invention consists in a pipe or way made of independent sections, each section having one flanged and one unflanged end, both ends being parallel and formed on a bevel—that is to say on a plane inclined to the plane of its bottom and top. The invention also consists of a pipe or way made in independent sections, each section consisting of two separate members, one above forming the cover and one below forming the main body of the pipe or way, each member having one flanged and one unflanged end, said ends in each being parallel and formed on a bevel, the bevel of the lower member being the reverse of the bevel of the upper. The object of the invention is to provide a pipeway or conduit for general purposes such as water-ways, ditches, sewers, etc., made of independent sections, the peculiar construction of each section rendering it possible to form tight joints and at the same time to readily remove any section or portion thereof for any purpose that may be required.

SNAP HOOK.—Frank White, Pomona, Los Angeles Co. No. 451,314. Dated April 28, 1891. The object of this invention is to provide a harness and rope snap made of a single piece of spring wire, the hinge of which is durable and of a character which will prevent it from being clogged.

TENSION AND CUT-OUT DEVICE FOR ELECTRIC RAILWAYS.—Byron Jennings, San Jose, assignor of one-half to James Brusie, Oakland, No. 451,326. Dated April 28, 1891. This invention is adapted for use in electric railways of that class in which the conducting wire extends through an underground tube or tunnel having a slot in the upper part through which connection is made between a trolley wheel which travels in contact with the wire and the motor upon the car from which the trolley is suspended. The object is to provide for a suitable tension of the conducting wire, so as to maintain it approximately in a straight line and provide the proper contact between it and the traveling trolley wheel, and a means for cutting out sections of the wire, so it may be properly tested to see if the insulation is perfect, or to detect the point at which the grounding may have taken place.

MECHANICAL PROGRESS

Elastic Cannon.

The segmental-tube wire gun is a new departure in cannon manufacture, which is just now attracting much attention. This gun is a tube of longitudinal steel segments wound with wire and encased in a jacket to protect the wire from small projectiles. The wire is wound under a tension of 50 tons to the square inch. The guns can be built in one-third of the time required to build other big guns, and can be put together in any steel works in the country. The recent test at Fort Wadsworth demonstrated that such guns can stand an extraordinary powder pressure. A 15-inch gun, it is claimed, would throw a shot 15 miles, and with such force at a short distance as to pierce a phenomenally thick target of wrought iron. Another novelty attracting attention is a rapid-fire six-pounder made for the Government, capable of sending a six-pound projectile a distance of at least five miles. The projectile is cone-shaped, made of hardened steel, and so great is its velocity when fired from the gun that it will perforate a six-inch steel plate at one mile without flattening or otherwise damaging itself. Although the gun weighs 848 pounds, it is so skillfully mounted that the merest touch of a finger sets it revolving about its axis, while the firing is effected by means of a trigger no larger than that of an ordinary revolver. The weapon can be handled so rapidly that a six-pound projectile can be sent toward the north and another sent toward the south long before the first shot has reached its destination. If this invention should prove a success after further and crucial trial, it will be a very important achievement.

The inventor, Jobu Hamilton Bedot enumerates the advantages which he claims for his invention as follows:

"There are several points wherein I think we have been able to improve materially on all the large guns now in existence. Working as we do, we obtain a degree of strength, toughness and elasticity in the steel used hitherto unknown. By winding the segments with wire, we are enabled to submit every part of a gun to the most rigid and exacting test, producing absolute uniformity and excluding the possibility of flaws and defects. Our guns can be made with ease and cheapness. There is not a steel plant in the country but that with a very slight addition to its facilities can make them. Inside of six months should occasion demand, we could, with the facilities at our command, turn out 500 completed guns yearly. This gun can be completed in one-third of the time that it takes to build a Krupp gun.

"We calculate that it can be fired at least a thousand times before any part of it gives out. Built-up guns, like the Armstrong and Krupp guns, cannot, as a rule, be fired more than 70 times. Besides, our gun can be fired ten times an hour, while the other big guns can with safety be fired only a very limited number of times in the same time. The greater pressure we are able to obtain insures greatly increased velocity. As a consequence, we can use shorter guns on shipboard without decrease of energy, while by our system, guns can be made of any length desired. For use in the field, we can make guns that will be light without loss of strength. For siege and defense, we can build strong and powerful guns, whose energy and range will be greater than have ever been obtainable in the past."

The inventor very generously refers to Lieutenant Whistler of the Fifth United States Artillery, who has rendered much assistance in developing and perfecting this invention.

A NEW SAW FOR CUTTING ARMOR PLATE.

A new cold saw for cutting steel armor plates is described by a Pittsburgh daily paper. It is in use in one of the largest plate mills and said to give results very much more satisfactory than the ordinary hot saw. It is described as simply a circular saw of fine steel, tempered somewhat hard, and about one-quarter of an inch in thickness at the periphery. It is ground slightly thinner at its center to clear itself easily in a deep cut. It is made to revolve at a slow speed, while the old hot saw was run at a high rate and did its work by means of the intense friction created rather than teeth. It cuts one inch a minute. The machine differs from the ordinary circular saw in this respect, that it is not the work that moves up to the saw, but the work is fixed stationary and the saw is made to travel along the table through it. It is driven by a worm wheel and screw of some four or five feet in length, along which it can be moved easily by hand-screw gear or by self-acting feed gear. The saw runs in a tank of acid, and the greatest care is necessary in regard to the quality of the materials in the solution, which is made up of ten pounds of whale-oil soap, 15 pounds of soda, two gallons of best lard oil, with water added to make 40 gallons of mixture.

A NEW BOILER RIVET.—It often happens in riveting boilers that the rivet bulges in the center, resulting not only in the separation of the plates but sometimes in the splitting of one or both of them. In order to obviate this defect, which very seldom becomes known until the boiler comes into actual use, a rivet has been devised which has a thinned waist, to allow for expansion, and the nucleus of the burr already shaped. The burr is thus practically

started before it receives a blow, and the fiber of the metal is already inclined toward the position it will be ultimately forced to assume. The result is that the rivet holes become properly filled with the slightly expanded waist of the rivet; the plates are closely united; the burr is well formed, and there is no danger of the plates cracking. The riveting is also effected with fewer blows, thus economizing labor.

MAKING BOTTLES BY MACHINERY.—A discovery has been made in the manufacturing line by a concern doing business at Woodbury, N. J., that is worthy of notice. For years glassblowers have predicted that bottles could not be made by machinery. The American Bottle Company, incorporated a few months ago, with works at Woodbury, has demonstrated, and is demonstrating, that the glassblowers are wrong. The new method is very simple. The glass is gathered in the usual manner and allowed to run from the rod into an iron cup, which holds the quantity needed for making the bottle. A hollow iron plunger at the bottom of the cup is pushed up through the mass, and the cup is reversed, leaving the glass in a plastic condition suspended from the hollow plunger, through which air is admitted. The cup, which is hinged, is then removed, and the movement of a lever admits a small quantity of air. The bulb is then flattened at the bottom and dropped into the mould, which is then closed and the air applied. This operation completes the bottle, and it is taken while hot to the annealing oven. By the old process the ring at the top of the bottle neck was formed by a second operation. This is done away by the machine method, and the bottle comes from the mould with a perfectly-formed ring, thus greatly lessening the cost of production.

MECHANICAL STRESS ON STEEL.—The result of investigations made by Oarus Wilson, and by him lately published, on the effect of mechanical stress on steel, shows that, in the case of uniform longitudinal strain on a steel bar, there is a strain of the molecules, also of the elements, and a production of flow by a strain of the elements. The elongation due to flow is, he says, the strain usually observed, and this may be either recoverable or otherwise; again, the strain of an element is made up of a uniform dilatation and a uniform shear about an axis parallel to that of the bar, and, therefore, the flow elongation consists of an increase of volume, together with a certain amount of sliding. The general conclusions arrived at by the author of these experiments are as follows: Mechanical strain produces an atomic disturbance in a bar, and this disturbance increases regularly with the stress; for small stresses the disturbance is only partly permanent, but as the yield point is approached it becomes wholly permanent; finally, the magnetic properties of a loaded bar are in general different from those of the same bar unloaded; but, notwithstanding this general fact, there is a certain stress, or range of stresses, over which the bar is found to have the same magnetic properties, whether it be loaded or not.

DESTRUCTIVE POWER OF BIG GUNS.—"Few people," says a naval officer, "appreciate the tremendous power of the blast caused by firing a big gun on board of a ship. An example of its effects was seen in some recent trials in firing the 67-ton gun of the new battleship *Trafalgar*, considered one of the three or four finest vessels in the British navy. The gun was pointed directly ahead, and fired with a charge of 630 pounds of slow-burning powder and a 1250-pound projectile. The blast produced by the rush of powder-gas and the shot was so tremendous that the plates of the fore-castle were forced in and the deck-beams bent out of shape, while almost every round carried away some fragment of the projecting portions of the ship, even when the training was to the right or the left. It is estimated that the vessel would be reduced to something very like a wreck were 25 rounds to be fired, either directly ahead or directly astern. This interferes with, or renders impossible, firing when either in flight or chase, and has caused our naval constructors to modify the plans for the projected battle ships, as it is not deemed desirable to have them sink from the discharge of their own guns.

CANS MADE BY MACHINE.—A machine that makes cans for a fruit-packing concern in California is just now attracting attention, says an exchange, on account of its great ingenuity. The machine cuts a piece of tin into four parts and then passes them to a feeder, where they are seized by a revolving wheel by which the can is formed. It is completely soldered by an ingenious process, after which the machine tests it by dipping it in the hot water and subjecting it to pressure. When finished by this marvelous machine, the can has no solder on the inside and is perfectly free from acids.

TO CLEAN MACHINERY.—A useful recipe for a mixture to clean the iron portions of machinery and ordinary tools is as follows: Take two to three cents' worth of paraffine, chipped fine added to one litre of petroleum in a stoppered bottle, which for two or three days should from time to time be shaken up until the paraffine is dissolved. To apply it, the mixture is well shaken, spread upon the metal to be cleaned by means of a woolen rag or brush, and on the following day rubbed off with a dry woolen rag.

SCIENTIFIC PROGRESS

THE CENTER OF POPULATION.—The center of population of the United States on June 1, 1890, as given by census bulletin No. 34, was in latitude 39° 11' 56", longitude 85° 32' 53", being a little east of Greensburg, Ind. The closeness with which the center of population, through such rapid westward movement as has been recorded, has clung to the parallel of 39° of latitude is very noticeable. The most northern point reached was at the start, in 1790; the most southern point was in 1830, the preceding decade having witnessed a rapid development of population in the Southwest; Alabama, Arkansas, Mississippi, and Louisiana having been admitted as States and Florida annexed and organized as a Territory. The extreme variation in latitude has been less than 19 minutes, while the hundred years of record have accomplished a movement of longitude of nearly 9.5 degrees. Assuming the westward movement of the center of population to have been uniformly along the parallel of 39° of latitude, the westward movement of the several decades has been as follows: 1790-1800, 41 miles; 1800-1810, 36 miles; 1810-1820, 50 miles; 1820-1830, 39 miles; 1830-1840, 55 miles; 1840-1850, 55 miles; 1850-1860, 81 miles; 1860-1870, 42 miles; 1870-1880, 58 miles; and 1880-1890, 43 miles, a total westward movement of 505 miles in 100 years.—*Railway Review*.

ANALYSIS OF AN ECHO.—To obtain, so to speak, an articulate echo, one that shall be a clear and exact repetition instead of a confused re-echoing of the speaker's utterance, requires that the speech shall be accurately timed in its delivery. An ingenious calculator has lately reduced the matter to an exact statement, based on the assumption that not more than five syllables per second can be distinctly uttered and clearly heard. The sound of each syllable has thus one-fifth of a second in which to reach the reflecting surface and to be returned by the echo, before the next syllable is pronounced. Taking the velocity of a sound at 1120 feet per second, the syllable can make a round trip of 224 feet in the one-fifth of a second which is allowed it; and the reflecting surface must therefore be at half that distance, or 112 feet. For obvious reasons, however, the combined effort of articulation and attention in such minute subdivisions of a second is scarcely possible in practice. The rule would seem to be more satisfactorily tested by the utterance in one second of five syllables in succession, followed by a pause of equal length. If the echo is 500 feet distant, the first syllable of the five will then return just as the last one has been spoken; and the last one will arrive just before the first of the next series starts upon its journey.

USEFUL INVENTIONS.—Among the recent experimental novelties brought forward are what are termed heat indicators, consisting of thermometers encased and protected by iron tubes provided with platinum wires, and connected to a system of electrical bells and indicators on a vessel's deck, by this means preventing spontaneous combustion in a ship's cargo. The effect of this arrangement, as claimed, is that in case of any undue heat arising in any part of the cargo, the mercury in the thermometers will go up, make contact with the platinum wire, and give an instantaneous alarm on deck, indicating at the same time the exact spot where the heat exists.

Another practical invention in this line is an article called alterion, for preventing corrosion in boilers, the interior being coated with this substance, and currents of electricity all passed through the boiler and from time to time reversed, the formation of scale being prevented by a layer of hydrogen gas, deposited on the inner surface of the boiler; the reversed currents reform the hydrogen into pure water, a thin layer of the latter being thus kept all round the boiler.

PECULIARITIES OF IRON.—Add carbon to pure iron and it becomes steel. Add a hydrocarbon to iron, and steel itself becomes so extensively modified that its properties are not recognizable. Thus steel may be as soft as pure iron. Add hydrogen, in varying quantity, and it has the quality of resilience, as in watch spring, or the quality of tenacity, as in the knife or razor, or may be given nearly the hardness of a diamond, as in a file. With steel at a low temperature, from 400° to 450° F., edge tools are produced, the color in the yellow shades; from 500° to 525° various sorts of springs are produced, color blue; while by heating iron to whiteness and plunging it into water, which is mainly composed of hydrogen, files are produced or forms even harder.

SPIDERS.—It is very seldom that any small insect escapes from the web of a spider, a fact which is not to be wondered at when it is considered that an ordinary sized anare may contain as many as 120,000 viscid globules. The spinner is constantly engaged in repairing injuries to the web inflicted by wind, stray leaves or captured insects. Once a day the whole anare is subjected to rigorous examination, and any broken or loosened threads are adjusted.

HOW A FOG MAY CAUSE A FIRE.—Fog does not very often cause a fire, but it has done so in the following manner: Water is nearly as good a conductor of electricity as metal. In a fog or rain, the insulating coating of the wires

becomes soaked with moisture. It is the exception and not the rule for this insulating coating to be perfect. Where the insulation is defective, the current can easily leap from one wire to another, or even from a wire to some other object, and cause flames to burst out. This very thing happens not unfrequently, and fires in cities have been the accompaniment of fog and rains.

CEMENTING IRON GRATING, ETC.—The following mixture has been used with great success for the cementing of iron sailing tops, iron gratings to stoves, etc., with such effect as to resist the blows of a sledge hammer. This mixture is composed of equal parts of sulphur and white lead, with about one-sixth proportion of borax, the three being thoroughly incorporated together, so as to form one homogeneous mass. When the application is to be made of this composition, it is wet with strong sulphuric acid, and a thin layer of it is placed between the two pieces of iron, these being at once pressed together. In five days it will be perfectly dry, all traces of the cement having vanished, and the work having every appearance of welding.

THE LIGHTING FLASH.—Until quite recently, all of the authorities concurred with each other in the opinion that a lightning flash was instantaneous; late experiments show that the flash is not infinitesimal, but that it lasts a measurable period of time. This interesting fact was ascertained by setting a camera in rapid vibration and exposing in it a plate so as to receive the impression of the flash. Upon taking out the plates, it was found that the impressions seemed widened out on the negative, showing that the negative had been moved during the time the flash was in existence.

BOTANICAL GARDENS.—In Europe, there are over 300 botanical gardens, displaying the vegetation of every clime and affording perpetual delight and information to the people. In the United States there is only one—Shaw's garden, at St. Louis. The west has taken the lead of the East here. But the prospect is, that in the course of a few years, New York City will have a magnificent botanical garden at Bronx park, rivaling in time even the royal Kew gardens at London or the Jardin des Plantes at Paris.

NAVAL OBSERVATIONS.—It is stated here that many leading astronomers of the United States are uniting their forces and will memorialize the next Congress to transfer the control of the United States Naval Observatory at Washington, from the Navy Department to the hands of a purely scientific and astronomical board. This is the outgrowth of dissatisfaction among various observatories growing out of the practice of the Naval Observatory of supplying telegraph companies, with time signals for commercial use.

THE ELECTRICAL SAW.—It has been noticed that platinum when placed in an electrical current, is heated to a dull redness. This fact is the basis of the invention of an electrical saw, which will cut quickly and neatly the hardest wood. The device is made of steel wire, upon which is deposited metallic platinum. By connecting this modified wire with the terminals of four Bunsen batteries, the platinum is heated to a bright redness, and the saw is ready for business.

STAR MOTIONS.—The moon revolves around the earth, and the earth, carrying the moon with it, revolves around the sun. Just so in a triple star system we behold one star revolving around another, and the two together revolving around a third. The resemblance goes even further, for the smallest star of the three revolves around the second in size, and that in turn around the largest.

HOW THE STEEL PEN WAS SUGGESTED.—One day, in 1830, when a working jeweler, Joseph Gillott, now the famous steel penmaker, accidentally split one of his fine steel tools, and being suddenly required to sign a receipt, not finding his quill pen at hand, he used the split tool as a ready substitute. This happy accident led to the idea of making pens of steel.

The old telephone wires in London, which were galvanized, and weighed 224 pounds to the mile, are now replaced by silicon bronze, weighing 36 pounds to the mile. It will, however, be interesting to note the results of wet, clinging snow, which usually plays such havoc with overhead wires of all kinds.—*Invention*.

BIRDS.—An American naturalist has made up a list of 210 birds, which are indigenous to Alaska, but also the English sparrow is not among them, and the people of that land cannot be blamed for declaring that the United States has no real sentimental interest in them.

The typical earthquake is preceded by a faint tremor which alarms birds and animals a few seconds before the violent convulsions set in, and which are followed by some longer waves dying away. The real beginning is very indistinct, a fact which still requires explanation.

An electrical expert says no light has been found that will penetrate a fog better than the old oil lamp.

ELECTRICITY.

DAMAGE BY LIGHTNING TO STREET CAR MOTORS.—Much damage has been done to various electrical street-car roads at the East from lightning, and of course very serious apprehensions are always felt by passengers on such roads, when in transit during thunder storms. Until quite recently, no device has been suggested to reduce the liabilities to such danger. The roads in question are run by the trolley system, with overhead wires. A short time since, an accident of this kind occurred, when a portion of the cars were on a down-grade, while others were on an up-grade, and all equally exposed; but the lightning entered only the down-grade cars. Subsequent inquiry, moreover, resulted in bringing out the fact that such was almost or quite invariably the case under such circumstances. The electrical superintendent of the road in question made a thorough inquiry into the reason why the lightning entered the down-grade cars alone. He soon observed that the "A" coil always remains charged, even when the motor is not running. Consequently, when the lightning got upon the trolley wire, it was free to pass down into the motors, and then broke through the insulation and jumped across to the cores. In the cars that were running, this discharge was checked by the high self-induction of the magnet coils, and what small amount could pass through was free to go to earth without injury to the motor. In the cars where the current was shut off, however, there was little of this checking action, and consequently the lightning jumped across to the core and went to the earth. The superintendent in question, who is more than usually ingenious in the matter of repairs, saw the point of the accident at once, and promptly changed the connections so that the "A" coil should not be charged when the motor is not in action, but should be cut off at the switch-box. Since that time the blue has not been struck, so that the efficiency of this arrangement has not been tested, but the arrangement certainly lessens the likelihood of damage to the motors. We gather the above particulars from a correspondent of the *Electrical World*.

SOLDERING WATCHES BY ELECTRICITY.—One of the wonders of electric welding is the wide scope in which it can be utilized. One of its most remarkable achievements is the joining of various metals which have hitherto defied the attempts to weld them perfectly. By this process brass and zinc can be fused together, and one of the specimens which has attracted a great deal of notice, and which is strikingly suggestive of the possibilities of electric welding is a single bar composed of four metals in equal quantities, namely, brass, German silver, copper and zinc. It is believed that this process may, in course of time, be applied to the welding of shafts for marine engines, and in the meantime it is being used for the most delicate work. It is now found that electricity can be employed in the process of soldering jewelry much cheaper than gas. A great deal of experimenting has been done in this direction, and the results have been to establish the fact that electricity is not only more handy for this purpose, but that the fusion of the metals is so complete that if they are subjected to a strain at any subsequent period they will break at any point rather than at the point of welding. —*Philadelphia Press*.

NEW AND OLD ELECTRIC LAMPS.—Since the electric light has come into such common use, it may be well to know how it affects the eyes. Dr. John H. Payne, a celebrated oculist, says: "Most persons who use the incandescent electric light like a new lamp, because the light is whiter and more brilliant than after the lamp has been in use for two or three weeks. This is wrong. It is this dazzling white light that harms the eye. An old lamp is the best, for in these the light has become changed to a pale yellow, which is the ideal color. Just as in noonday brightness human sight is not so clear and far-reaching as at the yellow sunset, so a new incandescent burner is not so good for the eye as the old one. An old burner, so adjusted and shaded that the light from it does not shine in the face, is the ideal artificial light. An Argand gas burner comes next. The use of the arc light should be confined to street lamps. Some store-keepers still use them, but they are terribly hurtful to the eye. This is because the intensity of the light is constantly changing, and this jumping of the blaze is much worse for the eye than the flicker of the gas-light. I have had occasion to treat a great many people for inflammation of the retina, caused by working by the light of arc lamps."

ELECTRICITY IN WARFARE.—Electricity is destined to play a great part in future warfare both on land and sea. No war ship with any pretension of modern equipment is without an electric plant. The heavy guns, which heretofore required the services of several lusty men to point, are now moved by an electric motor. The gun captain can himself, by moving a small lever located at the back of the gun, point it in any direction desired. The advantage gained is not so much in the fact that the gun can be moved quickly as that it is under the control of one mind. Complexity is giving way to simplicity, and in order to have every part of the ship do its work at the proper instant, the captain ensconced in the conning tower can place himself in communication with

any part of the vessel by means of the telephone. He must know just what every man is doing, and must, in fact, be the brain of the ship, while the electric wires are the nerves. —*Ex*.

DANGER FROM ELECTRIC WIRES.—Much hne and dry is being indulged in with regard to danger from electric wires, but when the matter is carefully inquired into it will be found that nearly all the accidents occur from cases of the most transparent carelessness on the part of either the sufferers themselves or those entrusted with work over them. Time, education, experience and improved devices to avoid the possibility of accidents will soon essentially do away with all danger in this respect; even now, these accidents are greatly magnified, and are in fact far less in proportion than are met with in parallel industries. By the gas consumers' report of Massachusetts for 1890 it appears that 107 persons lost their lives during last year from the effects of gas—more than ten times as many as were killed by electricity. Further comment is unnecessary.

AN IMMENSE DYNAMO.—A dynamo of 10,000-horse power is in process of construction at Deptford Station, London. Some idea of its size can be obtained from the fact that the armature will be 40 feet in diameter, with a shaft 36 inches in diameter. It will be driven at a speed of 60 revolutions a minute by two compound vertical condensing engines of 5000-horse power each.

USEFUL INFORMATION.

ASBESTOS is now used to make complete suits for firemen, it is said. Masks are made of asbestos, which are fireproof, and the heat from the hottest fire is said not to penetrate to the skin. Air is drawn from beneath the mask for breathing, so that the burned or flamed and smoke-laden atmosphere is not inhaled. Aprons and insulated coverings for the entire body are now constructed of asbestos. For domestic use sad-iron holders of asbestos may be bad, and with these the grasp of the iron, however hot it may be, never causes pain or burning. Plumbers welcome asbestos cloth for joint-wiping, and larger holders intended for use by smelters, molders and workers in metal generally are among the most recent uses of this mineral. Asbestos mittens to guard the hands are made for assayers, refiners, etc., and armed with a pair, the artisan or worker can grasp hot irons, crucibles and the like without discomfort. The mittens are sufficiently pliable to permit of small objects being readily poked up and held in the hand wearing them.

EXPORTING BEEF CATTLE.—Every beef animal that leaves the United States has its ear pierced. A fine wire passes through the hole, and attached to the wire is a tiny brass tag, not nearly so large as some of the ear pendents ladies used to wear. Upon the tag is a number and the initials "U. S. A." This shows that the animal has been examined by the United States Government Inspectors and is perfectly sound and healthy, and that even weak-stomached royalties may eat that beef with impunity. The Government deserves great credit for the pains it has taken to warrant the prime condition of American beef cattle. The influence of these thoroughgoing measures is already beginning to react favorably in Europe.

A GREAT many people are interested in knowing how to remove oil marks on wall-paper, where careless people have rested their heads. This may be done by making a paste of cold water and pipe-clay or fuller's earth, and laying it on the stains without rubbing it in; leave it on all night, and in the morning it can be brushed off, and the spot, unless it be a very old one, will have disappeared. If old, renew the application.

SAVING THE WASTE.—S. W. Taylor, says the *Oviedo Chronicle*, recently shipped 600 pounds of dried orange peel to a Baltimore firm. It took him about one week to gather this amount, and as he has been offered four cents per pound for it, he considers that he made pretty fair wages by it. The day is coming when the peel, the blossoms, the oulls, will all be utilized in California.

OLD GUNS.—A Belgian gun manufacturer says it is a mystery to him what becomes of all the guns made. They are not perishable or easily destroyed, yet, year after year, the great manufacturers have increased their works until the number of guns and pistols that are made each year is something enormous, and the trade, instead of decreasing, is constantly growing.

A NOVEL INCUBATOR.—D. G. Pitner has now 6000 eggs hatching in his hop-kiln, which he is using as an immense incubator. He is adding more eggs every day, and expects to have 8000 in before the kiln is full. Everything has gone on nicely so far, and the indications are that this novel hatching project will be a success. —*Sutter Independent*.

THE WEALTH OF THE UNITED STATES was assessed at nearly \$50,000,000,000 in 1880 and had nearly tripled in 20 years. Its actual aggregate in 1891 is probably very near to twice the great sum named.

GOOD HEALTH.

The Orange Cure.

The orange cure is not unlike the famous grape cure practiced in some parts of Germany. Oranges should be free as water. You take two or three, at least, before breakfast; and after breakfast, as you saunter out in the grove, you sample two or three more of the different varieties. There are always more or less of "drops." The juice contains the main curative principle. As with grapes, you must avoid seeds and skins; so with oranges. The more Navel the better, destitute of seeds and filled to the bursting with the rich orangeade. One reason why we would recommend the Navel is that you can regard the skin as a kind of cap, and drink your generous glass full of the pure juice even from one orange. We have often seen a Navel that would weigh a pound. A large orange of other varieties is liable to be coarse, and, having a coarse-grained pulp, which is not palatable but comparatively dry, so that you must cut several such oranges to obtain the amount of the healing juice that you get from the Navel; the latter, too, has a finer flavor than the large oranges of other species. On the whole, we give the preference to the Navel for all the purposes for which an orange is grown, and particularly in our orange cure.

"What will it cure?" Well, we have mentioned dyspepsia, but this has almost numberless manifestations and symptoms, and often is at the basis of coughs, bronchitis, liver trouble, kidney trouble, heart trouble, and is almost certain to involve one or more of these vital organs. Get the stomach and liver right in the way indicated and the kidneys will soon be healthy. The blood comes pure, the lungs work normally, the nerves tone up; headaches, backaches and neuralgia even pass off. The orange juice acts very directly to benefit the liver and all the disorders that may infect the alimentary canal. —*Exchange*.

HYGIENIC BREATHING.—The many systems of physical culture now practiced unite in a recommendation of slow and deep breathing, and of a frequent practice of taking long breaths, which will force the air into all the lung cells. One physician says that six breaths a minute make a profitable average. Women especially are inclined to take many short breaths a minute, and exhaust their force in rapid and imperfect lung expansion. There exists a difference of opinion among the best authorities in regard to the best manner of breathing, some recommending abdominal and some chest breathing for women. "Breathe from the diaphragm" is a rule given by one leader of a system of physical culture. In a paper read before a woman's club in New York, a novel exercise was mentioned. It was that of drawing deep breaths and walking very rapidly at the same time. The speaker said: "I draw a deep breath, walking very rapidly when I have filled my lungs, and I do not take another until I have reached a certain point in the block. The result is exactly as if I had been running hard. My blood tingles all over me and I seem to have brought every nerve and muscle into active play." There are many "breathing exercises," one of the best of which is that of taking a deep breath and swallowing the air, first one and then the other, and finally both while the breath is inhaled. The exercises which expand the chest are among the best offered by systems of physical culture, and their practice to-day by so many women, especially in Boston, is an encouraging promise of health for the mature as well as the young. —*Boston Journal*.

PINEAPPLE JUICE FOR DIPHTHERIA.—"Nature has her own remedy for diphtheria," says a Chicago man. "It is nothing more nor less than pineapple juice. I declare that I have found it to be a specific. It will cure the worst case that ever mortal flesh was afflicted with. I did not discover the remedy. The colored people of the South did that. Two years ago I was engaged in lumbering in Mississippi. One of my children was down with diphtheria, and the question of his death was simply the problem of a few hours to determine. An old colored man, to whom my wife had shown some kindnesses, called at the house and, saying he had heard of my little one's illness, urged me to try pineapple juice. The old fellow declared that in Louisiana, where he came from, he had seen it tried a million times, and that in each case it had proved effective. So I secured a pineapple and squeezed out the juice. After awhile we got some of it down the boy's throat, and in a short time he was cured. The pineapple should be thoroughly ripe. The juice is of so corrosive a nature that it will eat out the diphtheritic mucus. I tell you it is a sure cure." —*New York Tribune*.

ORANGE BLOSSOMS FOR CHILDREN'S AILMENTS.—Peter Arlmond informs the *Anahelm Gazette* that a tea made from orange blossoms is a good preventive of all the ailments of children, and is also a great invigorant for older people. It is not necessary to gather the blossoms from the tree, but when the fruit sets, the ground will be found to be white with the fallen petals. These are gathered by spreading a cloth for them under the trees. The petals may be dried and preserved indefinitely, but in the green state are also efficacious in warding off disease. Mr. Arlmond states that this tea

will greatly alleviate or do away with the ailments and disorders usually experienced by children and save thousands of dollars in doctors' bills. It is certainly a very simple remedy and easily attainable in California, and might prove valuable. We should be pleased to hear of any good results that might be received from such use.

STEAM BOILER NOTES

Efficiency of Steam Jackets.

The question of steam jackets is getting to be quite a vexed question of engineering. Experience shows that in some instances the steam jacket appears to effect an important saving, while in others no important gain is observable. Exactly what are the conditions under which it may be most profitably employed have never been very clearly shown. Evidently more definite literature or experience is needed in this direction. Perhaps the following brief hints upon this subject by an English engineer, Bryan Donkin, may be of some service to engineers in this direction:

When we consider how easily steam jackets are misunderstood, and how often misapplied by making them into air or water jackets, an inquiry may be expected to reveal a great variety of results, and much want of uniformity. Few people fix a steam-gauge on their jackets to check the pressures and temperatures, and to ascertain whether the steam supply to the jackets is large enough. A cook at the highest and lowest points of the jacket should also not be omitted, to test for steam or water.

The "quality" or dryness fraction of the steam used in the engine has no doubt a considerable influence, but unfortunately there is much difficulty in testing the steam, since no reliable instrument at a moderate price has been offered to the public.

Further, there is the important question of the temperature of the cylinder walls, and of all the internal parts exposed to the working steam. All these have a marked effect. These walls should be kept generally at the highest temperature available, and certainly hotter than the initial steam. With the same quality of steam, and with walls at two different temperatures, the hotter wall will doubtless yield the most economical results. Where the walls are of the same temperature, and working with steam of different qualities, the drier the steam the better will be the result. My experiments show that the temperatures of cylinder walls are some 30° F. hotter with steam in the jacket than without. An economy of 31 per cent, due to the jacket, was obtained with a small, fast-running, single-cylinder, condensing, vertical engine. For every pound of water deposited in the jackets, about five pounds were economized in the cylinder.

With vertical cylinders, it is not difficult to divide the barrel jacket water into two parts, and collect the water separately from the two vertical cylindrical surfaces of the jacket space—that is, from the inner and the outer surface. It is only the former which represents the useful heat going through the metal walls and keeping them hot; the latter shows simply the loss due to useless radiation, which should be reduced to a minimum.

BANKING FIRES.—The fire in a boiler was banked over night, and during one evening a considerable portion of the water leaked out. In the morning the fireman stirred up his fire and then noticed there was no water in sight, and considerably frightened, he drew the fires and waited for the engineer, not daring to put in water. The engineer did not get excited, but took a place of waste, wet it well, put it on the end of a poker and rubbed it over the boiler plates and appeared satisfied. "What do you do that for?" inquired the fireman, and from the engineer's reply he gathered that if the plates were overheated, the water left by the wet place of waste would show it by quickly evaporating, but if they were not overheated the water would remain on the plates. From this little test he satisfied himself that it was safe enough to fill up the boiler.

DON'T FORCE YOUR BOILER.—One very important cause of deterioration in boilers is due to the fact of their becoming too small to do the work without forcing, so that the pulsations of the engine cause a well marked succession of shocks on the boiler, which result in the weakening of the material. By placing one's hand on the head or shell of the boiler, the vibrations of the metal can be felt, similar to the rising and falling of a man's chest while breathing.

GRATE SURFACE.—If the grate surface under a boiler is larger than is necessary to burn the required amount of coal, it is neither economy, convenience, nor good judgment to retain the full surface, as better results, with less labor and more economy in fuel, would be obtained by shortening the grates to such an extent that from eight inches to twelve inches of fire would be required at all times.

FIRING BOILERS.—Those who think it is nothing to fire a boiler, should undertake it sometime on a boiler hard pushed to supply efficient steam, with burning screenings or similar fuel. It is one thing to fire with good, clean Cumberland, but quite another job to use the less valuable or free-burning fuels.

Passing Events.

The fact that the iron molders of this city who have been on continuous strike for the past 14 months, have at last asked the foundrymen to arbitrate with them on the differences, is taken as an indication that they are tired of the contest. The foundrymen have declined to arbitrate with the Molders' Union, as they do not wish that body to dictate as to employees in the shops.

Another large mining company, this time at Coeur d'Alene, Idaho, has adopted electricity as a motive-power for mill, hoist, pumps, compressors, etc., and expects to save 50 per cent over cost of steam-power. A good many other companies on this coast would do well to look into this subject with a view to economy in working expenses.

The mines on the Northwest coast in Oregon, Washington, and in British Columbia, are receiving more attention than ever before, and capital is coming to the assistance of the miners. There is a large area of unprospected country in the region referred to.

Reports from the Deep Creek country, Utah, continue favorable, and something like a "boom" is in progress. Judging from the reports in the Salt Lake papers, the district has a great future.

Rock Blasting by Electricity.

Rock blasting by electricity is acknowledged to be the most effectual, as a large number of holes can be exploded simultaneously, and better execution obtained from the powder than if the holes are fired independently. No time is lost waiting for smoke and fumes of several blasts to pass away. In case of a misfire, the advantage of electric firing is still more evident since, if the charges are not all simultaneously exploded, there can be no possibility of its exploding afterward; therefore there can be no danger in approaching the face at once to discover the cause. In subterranean work and very wet shafts electric blasting is indispensable, as the charge can remain several hours, even days, in water before firing, without deteriorating, thus giving time to complete the loading of holes, and to make the necessary preparations before exploding the charge.

It is a fact to be regretted that the majority of blasters who use electric appliances know little, or perhaps nothing, about the principle of electricity. It might, therefore, seem almost impossible that success should attend their efforts. In theory, this may be so; but in practice the blasters can often outdo the electricians in preparing and firing the blast. Very little has, however, been published to enlighten blasters in the use of electric appliances, but a recent catalogue by James Macbeth & Co. of New York, manufacturers of electric blasting appliances, contains considerable information on this point.

One of the cuts (see page 289) represents clearly the manner of connecting holes for firing by electricity. A is the hole in the rock; B, dynamite charge in hole; C, electric fuses in dynamite charge; D, connecting wire joining fuse wires together; E, leading wire from battery to fuse wires; F, electric-blasting machine or battery. This method is called "connecting in series," and is the system universally adopted in this country. The electric-fuse wire should be about the same length as the hole is deep; better to have the wire a little longer, that it may project above the surface of the hole after it is tamped, for the purpose of connecting it to the wire of the next hole.

Care should be taken when tamping the holes, not to injure or cut the insulation on the wires, as bare portions of the wire or bare joints should never be allowed to touch the ground; particularly so if the ground is wet. After the holes are tamped and made ready to connect for firing, take and separate the ends of the two wires in the first hole, leaving the outside wire for connecting with the leading or battery wire; then join the inside wire of the first fuse to the nearest wire of the second fuse; then the other wire of the second fuse to one of the wires of the third fuse, and so on until all fuse wires are connected. Then take the outside fuse wires of the two outside or end holes, and join them to the leading wire which goes to the binding posts of the battery, and fasten there by means of a thumb-screw.

If the holes are far apart, use connecting wire for joining fuse wires together. This connecting wire should be of the same diameter or size as the fuse wire. The leading wire should be at least twice as thick. Special care must be taken when making joints for connecting wires together, to have the ends clean and bright, and free from dirt or grease; this can be done by scraping them with a knife. After all bare connections are made, they should be covered with the special tape insulation, which can be applied instantly. The heat of the hand will cause it to stick fast and make a thoroughly waterproof joint.

Many blasts have failed by allowing bare connections to come in contact with the ground. The earth being a conductor of electricity, and offering less resistance, draws the current from the fuse wires. Batteries should be a safe distance from the blast—usually about 300 to 500 feet. All workmen should be at a safe distance before operating the battery to fire the charge. An important matter which is seldom thought of by blasters, is to examine the leading wire, to see that there are no cracks or breaks in it. Even new lengths of leading wire may be defective. It has been found so in long lengths, where the ends are held together or joined only by a heavy cotton braiding, which prevented the current from passing.

Another illustration represents the usual way of making joints. First cross the ends of

the wire, as shown in cut A, then twist the ends, as shown in cut B, being particular to twist close and tight, as a slack joint or twist is not a good connection. Be sure to have the ends clean and bright. Keep bare joints off the ground.

Few people stop to consider the position which an electric fuse occupies in electric blasting. It is the essential article in that system, and should be selected with great care and caution, for without a reliable fuse labor and material are lost. It is inserted in the dynamite charge, and is exploded by means of an electric current, generated by the blasting machine or battery. The electric current, passing through the wires, heats the platinum bridge in the fuse and explodes it, the explosion or concussion of which fires the dynamite in the whole. The Victor electric fuses here-with illustrated are made of single and double strength as desired. The copper sheet or cap contains a very sharp and powerful explosive, about double the strength of the best blasting caps. The system of soldering the platinum ends is done with a special automatic machine, insuring uniformity, and securing the miscellaneous explosion of each fuse, which is most essential.

The joint insulation tape is a very useful and convenient article for covering bare wire joints in blasting, either on dry ground or under water. Its composition is konite; a superior insulating compound. It makes a perfectly and thoroughly waterproof joint, and can be applied instantly. The heat of the hand will cause it to stick fast to the bare wire and it cannot be removed, except by cutting it off. It is put in half-pound packages, in widths of $\frac{1}{2}$ and $\frac{3}{4}$ inches. It costs but a trifle, and should be generally used by all blasters for covering bare connections.

The "Pull Up" magneto blasting machines are specially constructed to meet the requirements of those who desire to fire a large number of shots at one time. The operating device is quite simple. The hinged iron plates on the bottom of the box are made to stand upon with the feet; then by pulling up on the bar with one continuous stroke with both hands, the blast will take place. After firing, the bar will drop back into place ready for use again. One of the cuts shows a machine connected with a small electric lamp for testing the condition of the battery. The lamp will tell the miner the condition of the battery. By connecting the wires of the lamp with the battery, and operating the latter as if firing a blast, the lamp will show an incandescent light, or a white flash if the current is very strong. If the current is weak, it will only slightly redden the fiber on the glass bulb. If the battery does not even redden the fiber of the lamp, the battery is not in good order and will not fire a blast.

The "standard" tester, shown on this page, will tell the miner if the fuses, cones, connections, joints, or even the entire blast are right or not. The machine is intended to test the electric fuses or exploders before placing them in the charge holes to blast, to make sure they are perfect. To make doubly sure with the same machine, the entire charge can be tested before putting the leading wire to the battery. The connection being properly made, the ringing of a little bell in the tester proves whether everything is all right or not.

In electric blasting, leading wire forms a very important part, and great care should be taken to have it in good condition and in a convenient form to use. The Victor reel is a simple and practical device to keep the leading wire on; it is strong and durable, and handy to carry about. It is the only reel made, whereby there can be a continuous wire from the battery to the blast—both wires are separated on the reel and can be run off in any required length. The Victor reel will hold over 1000 feet of wire, 500 feet on each, and 5 to 10 feet in the middle to reach to the battery.

The Victor connecting-wire holder is a simple device, which will be found very useful and handy for carrying connecting wire to the blast. When connecting the holes, or when not in use, it can be set upon the ground without danger of having the spool or wire get wet or dirty, it will also prevent snarling or kinking of the wire when cutting off the quantity desired. It will also be found convenient in the shop or store. It is arranged to hold two spools, weighing two to five pounds each.

The Cruiser Monterey.

(Continued from page 289.)

The propelling engines are of the triple expansion type, 30 inches stroke, the high-pressure cylinder being 27 inches, the intermediate 41 inches, and the low-pressure 64 inches in diameter, which, with the vacuum, etc., are expected to develop, with steam pressure at 160 pounds per square inch and 150 revolutions per minute, 5400-horse power. There are two main boilers, made of steel, 11 feet 2 inches in diameter, with a length of 10 feet 7 inches, with four other tubular boilers in addition, and all designed for a pressure of 160 pounds.

The armament of the vessel is to be as follows: Two 12-inch breech-loading rifled guns with 13-inch steel armor protection; shield 8 inches thick; projectile weighing 850 pounds; powder charge 425 pounds; two 10-inch breech-loading rifles mounted on barbette, with 11 $\frac{1}{2}$ -inch steel armor protection; steel shields $7\frac{1}{2}$ inches in thickness; projectile weighing 500 pounds and powder charge 250 pounds.

There are to be also 54 six-pound rapid-firing rifles; four 37-millimeter Hotchkiss revolving cannon and two one-pound rapid-firing rifles. In addition to the above armament, she will have a 15-inch pneumatic dynamite gun, which will throw 1000-pound projectiles containing 500 pounds of dynamite or other high explosives.

The Monterey is the first ship of the United States Navy fitted with the Ward sectional boilers. They were found after exhaustive trials and experiments by the Navy Department to be the best type adapted for use on coast defense vessels. Much of their merit lies in the small space they occupy, together with speedy steam generation, economic consumption of fuel and the easy manner with which repairs can be made in case of accident.

The engines, boilers, and magazines, in fact all the machinery will be well protected by armor, 16 inches in thickness, rendering their safety almost certain from the inroads of hostile projectiles.

It will easily be seen that with the completion of "Cruiser No. 6," the "Oregon" and the double turreted monitor, "Monadnock," together with those already built and in commission, San Francisco will soon be able to turn out a fleet of war vessels, well able to protect herself and the California coast.

Exhibit of California Tin.

The exhibit of stanniferous ores and their metallo products from the mines of the San Jacinto estate, made in this city during the past week, attracted great attention. The show-rooms on Market street where the display was made have been constantly surrounded with a curious crowd. The exhibit referred to consisted of about two tons of commercial ingots of pure tin, each weighing about 65 pounds, with a great variety of smaller bars all bearing the company's brand, "Temescal." There were also blocks and stannite figures draped in rolls of pure white, of a silvery luster and of various gaudy colors; masses of dark brown ore liberally sprinkled with the yellow tin oxide, and such other products as tin ore and metal might show.

There was also exhibited as a product of this San Bernardino county estate, the ores of gold, silver, cobalt, nickel and copper, coal and fire clay. Numerous photographs were shown of the works at Cajalco, etc. One of these was taken at the time of President Harrison's reception at South Riverside, where a 20-foot pyramid of tin ingots was shown him. The President is seen standing at the base of this pyramid. The whole exhibit of this new industry of the State was very instructive.

TECHNICAL SOCIETY.—At a meeting of the Technical Society of the Pacific Coast, held in the California Academy of Sciences building, R. Hinoholiffe, consulting engineer of the Pacific Iron Works, read a comprehensive paper on the Hall hydro-steam elevator. F. Gutzkow had on exhibition an improved injector for raising liquids, especially acids.

The California Electric Academy will shortly move into room 52 of the Academy of Sciences building on Market street.

PART of the articles recently stolen from the State Mining Bureau have been recovered.

Thinolite Crystals.

In an engraving of thinolite crystals on this page, an interesting study is presented of some of the forms of deposition that have taken place in ancient times in the beds of Pyramid, Bonneville, Mono and Lahontan lakes, and in their successive layers alternating with the cone and crag-like masses of tufa deposited from the waters of sublacustral springs.

These deposits, layers and crystals, following each other in long periods of time, are read by our geologists, like the pages of an ancient

book, presenting many physical facts that enlighten the study of some of the formations composing the crust of the earth.

Thinolite is considered as an alteration of crystals, the original forms of which have been preserved, while their chemical composition has changed.

The name thinolite was first applied to this mineral by Clarence King in his Report of the U. S. Geological Exploration of the 40th Parallel (Vol. I, p. 508), in which Lake Lahontan was first described.

What the original altitude of the highest of the ancient beaches of Mono lake in Mono valley may have been it is now impossible to determine with accuracy. Considering the elevations surrounding the lake the maximum

height of the ancient beach above the surface of the water, and adding to this the present depth of Lake Mono, but not considering the amount of recent sedimentation that has taken place, we have 827 feet as, approximately, the maximum depth of the lake at the time the highest of the ancient beaches was formed.

Figs. 1 and 2 of the engravings represent thinolite from Lake Mono, California, (natural size) showing the grouping of the composite crystals.

Fig. 3.—Thinolite from Lake Mono (natural size), fragment of a large composite crystal, hansen crystals; compare with Fig. 12.

Fig. 10.—Thinolite crystal (natural size), showing cap-in-cap pyramidal structure similar to Figs. 27 and 28 (deposited in Lake Lahontan).

Fig. 11.—Thinolite crystal (magnified four times), showing resemblance in form to the Sangerhausen pseudomorphs; compare with Fig. 12 (deposited in Lake Lahontan).

Fig. 12.—Single Sangerhausen crystal, showing form and external markings (magnified twice).

Fig. 13.—Group of small thinolite crystals deposited in Lake Lahontan (magnified four times); compare with Fig. 8.

Figs. 14 and 15.—Transverse sections (nat-

Fig. 19.—Square pyramidal crystal (reduced one-half) which gave at the point indicated, the section Fig. 24; the surface has been made smooth by subsequent deposition of CaCO_3 (deposited in Lake Lahontan).

Figs. 20 and 21.—Skeleton crystals, (natural size) showing cap-in-cap structure, and thus revealing the line square pyramidal form of the original mineral. (deposited in Lake Lahontan).

Fig. 22.—Crystals (natural size) from the Domea, Pyramid Lake; the surface smoothed over by subsequent depositions of CaCO_3 , with sprutings from the edges and extremities.

Fig. 23.—Section (magnified eight times) of a crystal from the Domea, like that in Fig. 22, showing a diagonal and rectangular framework, partly crystalline, granular, partly amorphous, with layers of secondary carbonate opal like in structure.

Fig. 24.—Section (natural size) of the crystals shown in Fig. 19 cut transversely at point indicated; it shows the same framework of granular crystalline carbonate, partially filled in with secondary CaCO_3 .

Fig. 25.—Section (natural size) showing the usual framework partially filled in with secondary CaCO_3 and with encosive layers also around the outside (deposited in Lake Lahontan).

Fig. 26.—Section of a crystal from the Marble Butte, Nevada (magnified eight times), and showing the structure lines of crystallized carbonate, and also in the cavities the acicular crystals of aragonite (?) (deposited in Lake Lahontan).

Figs. 27 and 28.—Small pyramidal crystals (natural size) showing by dissection the cap-in-cap structure, and thus like Figs. 20 and 21, revealing the true pyramidal form of the original mineral (deposited in Lake Lahontan).

Arbitration with Molders Declined.

When the Molders' strike commenced in this city some 14 months ago, the foundrymen were anxious to arbitrate the differences, but the molders declined, so the contest went on. Meantime, however, the foundries have been supplied with men and the Union molders have been idle. This week a proposition to arbitrate has come from the molders and has been declined by the foundrymen, as the following correspondence shows:

Iron Molders Union, No. 164.

SAN FRANCISCO (Cal.), May 1, 1891.—To the Engineers and Iron-founders' Association of San Francisco, Cal.—GENTLEMEN: Finding that the time has come when steps should be taken by the parties directly interested to bring the trouble which has existed for the past 14 months between your association and this Union to a termination, we would respectfully ask that a committee be appointed from your association to confer with a like committee from this Union to arrange for an arbitration of all differences between the two bodies and the members thereof.

Trusting your association will give this matter due consideration and that a favorable reply will follow, I am, yours respectfully,

JOHN S. COLLINS.

SAN FRANCISCO (Cal.), May 6, 1891.—To the Iron-molders' Union, No. 164, San Francisco.—GENTLEMEN: In reply to your favor of May 1st, we beg to state that before the strike took place and at the beginning of it we were very desirous of arbitrating matters of difference between members of this association and your Union, but our overtures were declined on the ground that the questions involved were beyond the jurisdiction of your local body. Consequently we were compelled to seek molders elsewhere. Now, 14 months after you voluntarily left our employ, you express a desire to arbitrate differences.

We understand the question of arbitration to mean that when two or more parties who have differences to adjust are desirous of settling them in an amicable and friendly manner they select disinterested persons to pass upon the questions involved, so that a settlement may be had in a speedy manner satisfactory to all the parties concerned, and that was our desire when we first proposed arbitration.

Now, all business relations between the members of this association and the members of your Union having been voluntarily severed by you, there are no differences between us which could be adjusted by arbitration.

However, we desire to say that we have no quarrel with your Union. Your members can obtain employment in our shops whenever we have work to do. We are not fighting your Union, and do not intend to. On the other hand, we believe that, as employers, we have the right to make the rules which govern our shops, and if these rules are too onerous for any one in our employ they have a perfect right to leave us and seek employment elsewhere. We also believe that any American citizen has a right to earn a living, and that every California boy has a right to learn a trade and become of use to society and not a drone.

We also think that California should in the past have received the same consideration from the molders that is granted to foundries in other parts of the United States. All we ever asked was that we should be placed upon the same footing as foundries in the East; that is to say, "open" shops.

We will under no consideration, now or at any time in the future, arbitrate or discuss in any way the question of discharging the men and boys now in our employ. If you desire to settle the strike, you can instruct your members to apply for work. We know of no other question to settle. Hereafter if differences arise between us and the men in our employ we shall be perfectly willing to submit such differences to the arbitration of disinterested persons. Respectfully yours,

ENGINEERS AND IRON-FOUNDERS' ASSOCIATION OF CALIFORNIA.

IRA P. RANKIN, President,
By R. S. MOORE, Secy.

FORMS OF CRYSTALS IN THINOLITE.

made up of small acicular crystals in parallel position.

Fig. 4.—Transverse section of the crystal represented in Fig. 3, showing the same skeleton structure distinct in crystals, deposited in Lake Lahontan, from Pyramid lake, Nevada, (Figs. 14, 15, etc.).

Figs. 5 and 6.—Group of thinolite crystals from Lake Mono (natural size), showing the acicular form, and also the way in which the crystals are coated over with the secondary carbonate.

Fig. 7.—Group of small crystals (magnified four times), from Lake Mono, showing the same method of grouping common in the Sangerhausen pseudomorphs, as shown in Fig. 8.

Fig. 8.—Group of Sangerhausen pseudomorphs (natural size); compare Fig. 7.

Fig. 9.—Isolated thinolite crystals deposited in Lake Lahontan (magnified twice), showing resemblance in form and making to Sanger-

hausen crystals; compare with Fig. 12.

Fig. 10.—Thinolite crystal (natural size), showing cap-in-cap pyramidal structure similar to Figs. 27 and 28 (deposited in Lake Lahontan).

Fig. 11.—Thinolite crystal (magnified four times), showing resemblance in form to the Sangerhausen pseudomorphs; compare with Fig. 12 (deposited in Lake Lahontan).

63 & 65 First St., cor. Mission, San Francisco.
We would call the attention of
Assayers, Chemists, Mining Com-
panies, Milling Companies, Pros-
pectors, etc., to our full stock of
Balances, Furnaces, Muffles, Crucibles, Scor-
ifiers, etc., including, also, a full stock of
Chemicals.
Having been engaged in furnishing these sup-
plies since the first discovery of mines on the
Pacific Coast, we feel confident from our experi-
ence we can well suit the demand for these
goods, both as to quality and price.
Agents for the Morgan Crucible Co.,
Battersea, England. Also for E. G. Dennis-
on's Silver Plated Amalgam Plates. The plates
of this well-known manufacturer are thoroughly reli-
able, and full weight of Silver guaranteed. Orders taken
at his lowest prices. Our Illustrated Catalogue and As-
say Tables sent free on application.
JOHN TAYLOR & CO.

Nevada Metallurgical Works.

NO. 23 STEVENSON STREET,
Near First and Market Streets, S. F.
C. A. LUCKHARDT, Manager. ESTABLISHED 1880
Ores worked by any Process.
Ores Sampled.
Assaying in all its Branches.
Analyses of Ores, Minerals, Waters, etc.
Working Tests (practical) Made.
Plans and Specifications furnished for the
most suitable Process for Working Ores.
Special attention paid to Examinations
Mines; Plans and Reports furnished.
C. A. LUCKHARDT & CO.,
(Formerly Huhn & Luckhardt),
Mining Engineers and Metallurgists

Books on Working Ores.

BY GUIDO KUSTEL, M. E.
ROASTING OF GOLD AND SILVER ORES (Second Edition) and
the Extraction of their Respective Metals without
Quicksilver. By GUIDO KUSTEL, M. E. 1890.
This rare book on the treatment of gold and silver ore
without quicksilver is liberally illustrated and crammed
with facts. It gives short and concise descriptions of
various processes and apparatus employed in this country
and in Europe, and the why and wherefore. It contains 166
pages, embracing illustrations of furnaces, supplements
and working apparatus. It is a work of great merit, by
an author whose reputation is unsurpassed in his specialty.
Price, \$3, cloth, postage free. Sold by DEWEY & CO., Pub-
lishers, 220 Market St., San Francisco, Cal.
BY C. H. AARON.
AARON'S LEADERS GOLD AND SILVER ORES, the most
complete hand-book on the subject extant; 164 pages
octavo. Illustrated by 12 lithographic engravings and
four wood cuts. Fully indexed. Plainly written for
practical men. In cloth, \$3. Sold by DEWEY & CO., S. F.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the
"Explorers', Miners', and Metal-
lurgists' Companion."
A practical exposition of the various departments of
Geology, Exploration, Mining, Engineering, Assaying,
and Metallurgy.
Price, \$5.00 post-paid. Sold by DEWEY & CO., Publish-
ers, 220 Market St., San Francisco.
By J. S. PHILLIPS, M. E.
The work is divided into four parts—Rocks, Veins,
Testing and Assaying. The geological chapters are
intended to give miners a practical idea of the various
formations. The chapters on mineral veins are derived
from long observation, and the section on exploration
has been carefully considered. All that relates to dis-
crimination and assay of minerals has been kept as free
from formulae as possible. The work is written for
practical men, and all the explanations and descriptions
are clear and to the point. It is prepared that it is
useful to uneducated men as well as scientists.
**DEWEY & CO., PATENT AGENTS, 220
Market St., San Francisco. Elevator, 13 Front St.**

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, May 7, 1891.

Mineral trade continues fair. Crop advices are taken as a whole, favorable for a larger outturn of wheat than has been for many years past. Southern counties that were the hanner producers last year, will give way to Colusa and other counties in the Sacramento valley. The acreage this year is over 1,000,000 in excess of that of 1890. The money market is easy, but a large demand is looked for soon, which will continue well into the fall months. Among manufacturers there is a cheerful, buoyant feeling.

MEXICAN DOLLARS—The market shows more strength, with dealers asking an advance. Quotations are given at 78 1/2 @ 79c.

QUICKSILVER—Receipts the past week aggregate 380 flasks. The market is unsettled, with quotations ranging from \$43 to \$45.

SILVER—Department purchases so far in this month are reported as follows:

Date.	Oz. Offered.	Oz. Bought.	Price Per Oz.
May 1.....	739,000	350,000	\$.9760 to \$.9840
May 4.....	326,000	326,000	\$.9850 to \$.9870

With the government resuming monthly purchases of silver, the market shows more strength. To the failure in last March of a large financial firm in India and the unsettled conditions of affairs between European Governments are traceable much of the depression in the silver markets abroad. We still maintain that before the fall months pass, a much higher range of prices will be witnessed in this country and Europe. This assertion is based on the statistical position of the metal and an undoubted large demand for India to meet wheat purchases. The higher prices ruling for wheat, calls for more silver in which to make payments. Everything in the United States points to either the re-monetizing of silver, or else to more favorable legislation, and this, too, soon after Congress meets in next December.

BORAX—The market is fairly steady at full prices.

LIME—Receipts the past week aggregate 5678 bbls. The market is fairly strong, with a good home and export demand ruling.

LEAD—A consignment of 494 pigs came to hand the past week from London, England. The market is said to be in the same unsatisfactory condition heretofore reported.

TIN—The consumption of tin is quite large, but the stock here and to arrive is largely in excess of this year's requirements. Oregon and this State will take increased quantities for fruit canning. At the East, a promised large fruit crop, if realized, will demand increased quantities of plate.

COPPER—Markets throughout the world are bearish. Consumers appear to restrict their wants. European money markets and political complications are against holders.

IRON—The market is reported essentially unchanged. Shotts No. 1 is again in market. Cargo fleet is selling at \$27 per ton spot.

COAL—Imports the past week aggregate as follows: Nainaimo 4904 tons; Newcastle, N. S. W., 4315; Sydney, 2315; Glasgow, 2333; Tacoma, 2000; Departure Bay, 2400; Seattle, 2300. Total 20,567 tons. The market shows a steadier tone. There is a growing impression that no lower prices will rule for sometime, and perhaps not this year. The consumption for steam purposes is not only very large, but promises to increase in the near future. After Australia markets her wheat surplus, vessels from there will be offering more freely for coal loading for this port to take advantage of our large crop of wheat. The consumption of domestic coals up north is very heavy.

Eastern Metal Markets.

By Telegraph.

New York, May 7.—The following are the closing prices the past week:

Silver in Silver	London.	New York.	Copper.	Lead.	Tin.
Thursday.....	9 1/2	13 75	4 20	19 65	
Friday.....	9 1/2	13 75	4 22 1/2	19 80	
Saturday.....	9 1/2	13 75	4 22 1/2	19 85	
Sunday.....	9 1/2	13 75	4 22 1/2	19 95	
Monday.....	9 1/2	13 75	4 22 1/2	20 05	
Tuesday.....	9 1/2	13 75	4 22 1/2	20 05	
Wednesday.....	9 1/2	13 75	4 22 1/2	20 00	

Of Borax there is a light supply, California being wanted at \$4c for concentrated and \$3c for refined and powdered in car lots. Quicksilver is quiet and easier. Tin is stronger, as is Lead. Copper continues easy and unsatisfactory in holders. Iron is reported firmer.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

BRICKS RANCH M. Co., May 4. Capital stock \$1,000,000. Directors—C. S. Shattuck, H. O. Greenhood, Hartley Williams, Calvin W. Kellogg and J. Dewing.

CALIFORNIA AND WASHINGTON INVESTMENT Co., May 4. Capital stock \$1,000,000. Directors—H. C. Barrow, C. E. Mayne, N. R. Gregory, J. E. Shepard, Geo. A. Turner and E. B. Barrow.

EDISON S. M. Co., May 6. Capital stock \$500,000. Directors—L. Glass, J. Wolff, B. W. Bates, M. Jones and F. E. Luty.

Mining Share Market.

Mining shares the past week showed continued activity at steady advancing prices up to Tuesday for Con. Virginia and its satellites, but shares in the Middle and Gold Hill mines did not appreciate much. On Tuesday afternoon the Middle stocks began to harden, and gathered more strength the next day which resulted, in the afternoon of yesterday (Wednesday), in quite an advance. In this up move the Gold Hill stocks sympathized, with Overman exhibiting the most vitality. The advance in Con. Virginia from \$6.37 1/2 a share on March 6th to \$20.50 on May 5th, has been effected so quietly, and in such a mysterious way as not to attract much attention. Toward the close some of the commission brokers report an increase in Con. Virginia shares held by them, but no increase in other stocks. This seemingly indicates that the pool is selling the former at present prices, and why not, for there is a good profit in sight. At \$20 a share the aggregate value of the mine is over \$4,000,000. This is a good round sum, when it is considered that in the forepart of January of this year the shares sold below \$2.50 which made the mine aggregate in value in that month less than \$500,000, and no more ore is in sight now than was known to be by the pool at that time. While other stocks have not advanced proportionately as did Con. Virginia, yet on an average their shares are selling now for fully three times more than they did the latter part of December 1890. Mining shares are not only higher now, but it looks as if they will go still higher, so as to allow the pool to unload at a good round profit, then look out for the old story—a good break and nearly all outsiders financially hurt, if not ruined. Persons who play at other persons games have only themselves to blame, and can not enlist the sympathies of those who are strong minded enough to let insiders, for the want of other prey, feed on each other. The work going on in the mines is of a still more exciting character, and dealers can prepare themselves for strikes and higher assays in the near future, provided they can not peddle out the stocks, without resorting to big hull stories or measures. In outside shares trading has been and continues light. It looks as if they are being concentrated for the usual summer bull campaign.

The market opened this (Thursday) morning quite active, with considerable more trading in Middle and Gold Hill stocks. After call, the prices shaded off under heavy sales. The market has a healthy look, as if the pool is standing under it preparatory for higher prices than have been reached on this deal.

From the Comstock mines, our advices are of a more encouraging character than has come to hand for some time past, particularly from the Middle and Gold Hill groups. The work that has appeared to be dead work is now giving place to active prospecting. In several, new crosscuts have been started to run for the west ledge. This work will be watched with the greatest possible interest, for in two or more of the mines they are liable to run into rich ore, and enough to make a deal so as to peddle out stocks, provided the public buy. In Andes, the work under way appears to be to develop the old Burning Moscow ground. It is high-grade ore. The work in the other North End mines and also Middle mines is of a favorable character, all of which has heretofore been outlined in this department of the PRESS.

From the outside districts, our advices are of a more encouraging character, and was it not for the activity in Comstock mining shares, the Tuscarora, Bodie and Qujiotoa stocks would be selling at much higher prices than are now ruling.

Assessment Notices.

GRAY EAGLE MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Placer County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 3d day of April, 1891, an assessment, No. 23, of Three (3) Cents per share, was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 11, No. 303 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 9th day of June, 1891, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.
A. W. BARROWS, Secretary pro tem.
Office, Room 11, No. 303 California Street, San Francisco, California.

INYO MARBLE COMPANY.—LOCATION of principal place of business, San Francisco, California. Location of works, Keeler, Inyo County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 30th day of March, 1891, an assessment (No. 12) of Ten Cents per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, 132 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 12th day of May, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 24th day of May, 1891, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
G. W. LUCE, Secretary.
Office, 132 California Street, San Francisco, California.

CARMELO LAND AND COAL COMPANY. Location of principal place of business, San Francisco, California. Location of works, Monterey County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of April, 1891, an assessment, No. 3, of Fifty Cents per share, was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 9, 324 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1891, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on TUESDAY, the 16th day of June, 1891, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.
W. T. BAGGETT, Secretary.
Office, Room 9, 324 Pine Street, San Francisco, California.

GOLD MINES

—AND— STOCK IN MINES FOR SALE.

Dividend-paying Mines from \$150,000 up.
Undeveloped Mines from \$10,000 up.
Undeveloped Mines on Hand.
Stock in Dividend-paying Mines from \$1 up.
Stock in Undeveloped Mines now being
opened from 25 cents up.

All situated in the GRASS VALLEY MINING DISTRICT, the Oldest Quartz Mining District as the Pacific Coast, and the Richest and most Permanent in the World. The mines of this district are practically inexhaustible, as nearly half a century of constant working is proof. Grass Valley has the deepest regular dividend-paying gold mines in the world, and the end is not yet, for these same mines are as rich to-day as at any time during their history.

Gold mining, especially in Grass Valley, when under honest and scientific management, is one of the safest and most profitable of all American Industries. It is a business that will return annually a profit of from 100 to 300 per cent on the investment. Mining is a science acquired only by years of study, combined with practical experience. Therefore, failure is the rule whenever the management is ignorant and unscientific.

The undersigned is a practical scientific and successful miner, has made mining a life study and vocation, is honest and trustworthy, and will not, under any circumstances, recommend or deal in any but valuable paying property and properties that will develop dividend-payers.

No Wildcat Mines; no Sharp Practice; no reasonable chance for loss; Honesty and Square Dealing Guaranteed. Correspondence solicited. Full particulars by applying to

S. B. FOWLER, Supt. Hartery Mine,
Grass Valley, Nevada Co., California.

BAND COUPLING.
Malleable Iron. All Sizes.
These Couplings are the best in the world, most powerful and cheapest. They have a ball and socket joint, tight and left screw and work freely. We use them extensively in our Tank Building Department.

WELLS, RUSSELL & CO.,
Mechanics' Mills, Cor. Mission & Fremont Sts., S. F.

A LIBRARY FOR \$1.00

Five books in one. Worth its weight in gold to every mechanic. The very latest information for 20 different trades. This wonderful book contains 675 pages absolutely teeming with rules, tables, secret processes, and new information that cannot be had elsewhere for less than \$25.00. The Model Steam Engine—How to Read an Indicator—The Westinghouse Air Brake—Blacksmith's and Machinist's Tools—Practical Mathematics Simplified—Tin and Sheet Iron Worker's Manual—Carpenter's Manual—Points for Painters—Magnetism and Electricity—How to Get a Patent—A Mechanical Dictionary. Everything fully explained in one handsome volume and guaranteed to be absolutely correct. Send \$1.00 for a copy bound in silk cloth, or \$1.50 for Morocco binding. With each copy of the book we give free a complete working chart for setting gear teeth. The regular price of this chart is \$1.50. **AGENTS WANTED.** Write for terms **LAIRD & LEE, Publishers, 263 Wabash Ave., Chicago, Ill.**

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.

121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS. Varying from the fraction of 1 up to 15 and 20 horse power, unequalled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

THE PELTON WATER WHEEL CO., 121-123 Main Street, San Francisco, General Western Agents.

The Oldest Quartz Districts.

It is worthy of note that the oldest quartz district in California is to-day the most prosperous and best-paying one. This speaks volumes for the reliability and lasting qualities of gold mines. It was in 1850, one year after the discovery of placers on Wolf creek, that they began to work gold-bearing quartz in Grass Valley, Nevada county, and this was the first work of the kind, not only in California, but on the Pacific Coast of the United States. And yet to-day, Grass Valley district is the center of the gold-quartz industry of California. It has the best mills, the best machinery, the largest number of producing mines, the deepest mines, and the mine that has paid the largest number of consecutive dividends in the State. The progress and development has been steady and sure, and made in the face of many attractive excitements elsewhere, which have taken men away; but the district has kept its reputation for safe and fairly reliable returns.

The Grass Valley Union says that the reason for the good reputation of the district is to be found in the adoption of the most improved methods of amalgamating, concentrating the sulphurets, which were permitted to go to waste, the introduction of water power and especially by deep working, which has proven the reliability and strength of the ore veins. In early years the workings were superficial, and the machinery light, and although remarkably profitable results were in a number of instances obtained, a want of capital in many cases prevented the depth of exploitation that was necessary to make a mine. Later experience has shown that such properties would have had a profitable life if stronger machinery and sufficient capital could have been commanded, and now there are very few who doubt that the district has many unprospected and undeveloped veins that in coming years will be known as valuable mining properties. A long list of mines may be named, among which were and are the Massachusetts Hill, Gold Hill, Scadden Flat, Allison Ranch, Eureka, Idaho, Empire and North Star, that have yielded many millions of dollars, but it is considered not improbable that other mines now operating or at present idle will have an equally

prosperous career. The district although the oldest on the coast is yet young in its possibilities as a gold producer, and from what has been accomplished and what the future promises, a century may not exhaust its riches.

A Bryan Mill Plant.

The Bryan roller mill is a modification of the well-known Chili mill, arranged for continuous wet crushing. The mill consists of an annular mortar containing fixed steel dies arranged in the path of the three crushing rollers, which, in the five-foot mill, are 45 inches in diameter, seven-inch face, and weigh 3050 pounds each. Their axles are fixed in them and journaled on a central revolving table attached to and driven by the belt pulley, making a very direct application of power.

The four-foot mill has a similar arrangement of dies, but smaller rollers, weighing 1200 pounds each, exclusive of the drum, which rests on their periphery, adding to their weight and driving them by friction. The crushing weight of the rollers can be increased as desired by loading the tank driving pulley.

These mills, which are made by the Bladen Iron Works of this city, have an unusually large area of screen surface, permitting the free discharge of pulp and preventing sliming. Many prefer these mills to stamps, for the reason that they are portable and quickly and cheaply erected, require less power and a less first cost. The accompanying engraving shows a complete

ELECTRIC TRAM CAR FOR MILLS.

Bryan mill plant arranged for free-milling gold ores.

An Electric Mill Tramway.

One of the earliest applications of the Thomson-Houston motor to tramways is shown in

the accompanying illustration. The tramway which runs from one building across a bridge, and the entire length of another building, is about 800 feet in length, and has a grade of about three per cent. The single overhead-wire system is used, the rails serving for the return current. The duty of the motor is to transport about four tons. The success of this installation is unquestioned, and it has been clearly shown how much time and labor can be saved by the use of such tramways in mill work. Anyone can readily see the advantage of a narrow tramway running the entire length of each floor, by means of which materials can be moved as desired.

Nearly every large mill is now equipped with a lighting plant, rendering it perfectly feasible to devote a portion of the current for operating tramways in various parts of the building, thereby facilitating the handling of materials and supplies at less expense and labor than could be accomplished by any other method. Around quartz-reducing plants, an electric tramway of this kind would be of the greatest convenience.

THE California World's Fair Commissioners will not consider applications for positions, nor fill any offices until the July meeting in this city.

BRYAN MILL PLANT FOR WORKING GOLD ORES.

Observations in Colorado and Utah.

Mineral Display at World's Fair.

[Written for the PRESS by ALMARIN B. PAUL.]

While letters from the various sections of California may be more interesting to your readers, yet possibly a line from Colorado will not be devoid of interest. I have now been here two weeks and have picked up some ideas among mining men and the various works. There is one fact that forcibly impresses itself upon my mind, and that is, Colorado has by all odds more advantages for mining capital than California. The hotels here are continuously filled with Eastern and Western capitalists, and Colorado's prosperity in the past few years has been quite a loadstone for drawing in much money for mining and other investments. It has forced itself on my mind very strongly that Californians need not have the "big head" as regards the point of their being the only properties capital should invest in, or that they can make capital more safe. The fact is, there is a great deal of life and enterprise in Denver, which causes no especial desire to reach out for better things elsewhere, especially as regards real estate and merchandizing. Here are two very large smelters. When I say that at the Hill works I counted 30 chimneys, you can form some idea of the expansiveness of the establishment. The Grant is also a very large concern.

The mining interest of Colorado is advancing steadily. Her gold and silver output for 1890 was many millions in excess of California, and the prospects are that 1891 will over-reach 1890. While here I have not only inspected the large smelters, by courtesy of proprietors, who gave me unusual advantages, but gave some attention to the McArthur-Forrest process for treating ores by cyanide. This process was first brought out in Scotland, large works being operated there; also in New Zealand and South Africa. The company in Denver, of whom Senator Tabor is president, Leonard Gow vice-president and L. L. Wiswall secretary, hold the right for the United States. This company has erected a ten-stamp mill with all the necessary appliances for treating from 15 to 20 tons per day, and as far as I have investigated the process, it is not too much to say that there is enough reality in it to present itself very favorably to my mind.

From what I have been shown as to the per cent obtainable in a very simple way, it is a system that Californians may regard as worthy of their consideration and as having passed the experimental stage. I will not undertake to give any explanation of it, as any of your readers can get pamphlets which will fully enlighten them by writing to secretary of company, Tabor Opera-house block, Denver, Colorado.

There is a Board of Brokers here who have about as much jaw and can hallow as loud and quick as the pine street bulls and bears. Stock listed on the Board is classified as dividend and non-dividend stock, and there is a constant and satisfactory business done by the Board.

The mines listed embrace no Comstock line, but all localities are operated in, so there is no see-saw in their movements "on the line."

As to mining machinery, I have seen but very little new—in that California is unquestionably ahead. Notwithstanding I make the observations I do, it is just to say that California to very many is a desirable State to visit and live in; fruits, flowers, and climate are the main attractions.

Now as to Salt Lake, Utah, it has not so much to show as Denver. At this time there is quite a stir about the Deep Creek mines, in Southern Utah, and many are going hither. The ore thus far brought in gives good backing for the tales told of that locality. This mining stir is stimulating prospecting in other sections, and the prospects are that Utah will go ahead rapidly from now on, from the simple fact that from now on there is going to be more bullion produced. The farmer, merchant, commercial man or real estate operator seldom gives a thought to the mining interest. He "wants nothing to do with mining," but where would they be if there should be a stoppage of the production of the precious metals? There is a general interest, in both Colorado and Utah, in their mineral exhibit for the World's Fair, and now while I think of it, what is California proposing to do? Of the \$300,000 appropriated by the State, how much is going to be set aside for the mineral exhibit? It is not to be supposed that the meager appropriation to the Mining Bureau is to make the exhibit as well as run that institution. The miners of California want to demand their share of the State's appropriation, or let the making of an exhibit have the go-by.

The mining interest has been imposed upon by the Granger and railroad landed interest long enough and unless they see to it, all of the "grand display" will be more largely in the interest of land manipulators. The Mining Bureau, is the proper institution, in connection with a few representative mining men from every mining county of the State to have charge of collecting, and making the mineral exhibit of the State. Not less than \$50,000 of the State's appropriation should be devoted to the mineral exhibit, and what there is lacking over that the mining counties would appropriate. It is advisable to have this question of how much is to be set aside for the Mining Department settled as soon as possible, for then miners can see if there is to be any encouragement

for them to go ahead for a grand display. The mining element is in no very especial good mood for hooming the general landed interest, and unless there is a spirit of liberality shown, there will be no effort made to display the vast wealth stored in our mountains. These sentiments are simply the echo of what I pick up on the wayside. Colorado is going to lead off in the mineral display, and to equal her California has got to do her best. The fact is, if California really tries, she can have the most attractive display if not the largest, and this will be so from the fact that more gold would glitter in her display along with her variety of base metals, building stones, etc., etc. As I view it (from past experience) there is no time to fool away in getting to work for the fair, so let the powers that be, say how much of the \$300,000 appropriation is to be set one side for the mineral display. Taking the new discoveries, the output of silver in Colorado and Utah, which latter will exceed her last year's product in silver largely, there is going to be too much silver for the gold product of the country unless some big gold find comes to the rescue.

There is no doubt in my mind but gold properties will soon be more in demand than for many years in the past. There is no discount on gold and there is no such thing as balancing the two metals when the product of silver is much in excess of gold. More gold mines must be worked to do it.

Academy of Sciences.

At the recent meeting of the California of the Academy of Sciences the whole staff of teachers of the Leland Stanford, Jr., University were proposed for membership, as follows: Prof. D. S. Jordan, President of the University; Prof. C. H. Gilbert, Prof. W. H. Campbell, Prof. O. P. Jenkins, Dr. J. G. Brame, Prof. Joseph Swayne, Prof. H. B. Gale, Prof. C. F. Marks, Prof. G. M. Richardson and Prof. F. S. Fritz.

Prof. Carl Lumholz, who achieved fame by his account of life among the Australasian abnatives, read an interesting account of his explorations in the Sierra Madres of the State of Chihuahua. He thought it the richest country on the North American continent for archaeological research. He related something of his discoveries in the botanical line, and stated that he had found imbedded in clay a huge horn of some gigantic species of bison now extinct—so large that it had to be sawed into three sections to be removed.

G. P. Rexford read a paper on "Some Indian Hieroglyphics at Swansea, Inyo County, Cal." His account of these curious examples of picture carving on the rocks was illustrated with some capital photographs.

E. J. Molera read a paper on Gen. Y. Banez, who had been President of the International Board of Weights and Measures.

Electric Transmission of Power.

The Clear d'Alene Company of Idaho have under construction a power plant which, considering its extent and the variety of work to be operated, will be one of the most important installations of a mining character yet made.

The plant is located on Canyon Creek about 1½ miles from the mill and mine of the company and consists of two 225 horse-power Edison generators driven by Pelton wheels running under 690 ft. head. The mill machinery will be run by an 80 horse-power motor helted direct to the main shaft. The compressor will be run by a 60 horse power motor helted to fly wheel; the hoist will also be run by a 60 horse-power motor geared direct to present driving shaft. The pump located on the 500 ft. level will be run by an 80 horse-power motor geared direct.

The entire plant has been planned to connect with the machinery already in use now operated by steam. It is expected that the operating expenses of the company will be reduced full 50 per cent when the new power station is in running order.

SANDING SAMPLES.—Two of the most prominent ore-samplers in Colorado have just been detected in one of the most extensive steals ever made from a mining company in the Aspen section of the country. They were handling 100 tons of ore daily of the Compromise Mining Company and about as much more in the aggregate from other small companies. Their method of robbing the producers was by putting sand in the sample that was divided, half to be returned to the mine-owners and half to be assayed at the sampler, by which means they largely reduced the percentage of lead and silver in the sample and ran it high in silica, making the cost of treatment much greater. By putting the same amount of sand in both samples, the assay of the mining company's chemist always tallied with that of the assayers at the sampler. Then they would make out a statement to the smelters, after settling with the Compromise Mining Company, to correspond with the real value of the ore. In this way in a few months they swindled this mining company out of \$30,000, and when caught in the act of putting the sand in the sample confessed to all their peculations.

PROF. BARNARD of the Lick Observatory has rediscovered Woll's periodic comet. This is the first return of the comet to its perihelion, and its reappearance has been looked forward to with great interest.

Dealing in Silver Bullion.

The bulk of the silver product of the United States comes from a number of large smelting works, some of which are the property of and are operated in connection with the mines from which the ore they treat is raised. The largest concern of this kind in the United States is, however, independent, purchasing ore at various mines, the general process being to buy ore on an assay value of the precious metals it contains. After treatment in the smelter, the silver bullion comes out in a form known as commercial bars. These are generally large oblong slabs of metal, weighing on the average 1000 ounces. Of course other supplies to a limited extent furnish part of the bullion dealt in the New York market, such as the melting down of old silver or of foreign coin. But the bulk of the supply, as already stated, is the product of the smelting and reduction works of the country. A silver market per se does not exist. The silver product of the country, or at least 90 odd per cent of it, passes through the hands of a few firms and banks in New York and San Francisco, which possess the experience and the facilities for handling it, and which make a specialty of the business. There are probably not a dozen establishments engaged in it to any extent, and three or four houses it may be confidently stated, monopolize the greater portion of the trade. Silver is consigned by smelting and mining companies to the bullion dealers or to the few banks which attend to this kind of business, who dispose of it in the market, sell it to the Government, ship it abroad or buy it themselves, and act as agents or the consignees for the principals.

Commercial bars averaging about 1000 ounces each are usually .999 fine; that is to say, transactions in them are made upon that basis, and bullion shipped from the well known smelters is accepted as of that fineness, which corresponds to the United States coinage standard. A certain number of bars are sent to the Assay Office and converted into United States assay bars, rather thin bricks of silver weighing about 200 ounces each, bearing the United States Assay Office stamp of weight and fineness. These are in demand for commercial purposes; silversmiths and others prefer them on account of the guarantee of fineness. Silver bullion shipped to Europe, however, is usually taken in the form of commercial bars. They are simply carted to steamships and placed in the treasure-room for transport, it being very unusual to pack silver bullion with the same care that is bestowed upon its more precious fellow, gold. Commercial bars also form the bulk of the stock held at New York against which silver bullion certificates are issued. The bullion held against these certificates is considered as 1000 fine, although it is the practice to transmute the figures, 1000 ounces of silver .999 fine being represented by 999 ounces 1000 fine. The price of silver in the market represents the figures at which it can actually be sold, either for export or commercial purposes, it being the selling quotation of leading bullion dealers. Until recently, of course, the price was fixed in New York by parity, at current rates of exchange, with the price in London. The London quotation itself is made in the same way, the bullion market there being, in fact, the transactions and figures of a few houses and banks which make a specialty of such business, dependent of course, on rates of India exchange, the relative advantage of shipping silver to the East in place of remitting exchange, and the demand for coinage purposes from India, China, or European countries. It is to be observed that the English standard of fineness for silver is .925 fine, so that American prices represent an allowance for this difference of .075 in fineness, as well as for the rate of exchange, which may vary from day to day.—*Bradstreet.*

STEPS TO CIRCULATE SILVER.—The first of the steps contemplated by Secretary Foster for getting the subsidiary coin now in the Treasury into circulation were taken May 1, when the following notice, signed by United States Treasurer Neheker, was prepared at the Treasury Department, and will be sent to the banks and bankers throughout the United States: "The coinage of standard silver dollars authorized by the Act of February 25, 1878, has been discontinued by the Act of July 14, 1890. The Treasurer finds it inconvenient to furnish them otherwise than in the redemption of silver certificates or treasury notes, but will forward silver half-dollars, quarter-dollars or dimes to any address free of cost for transportation, by express, in sums of \$200 or more, or by mail, in packages of \$70, in exchange for any other kind of money deposited in the Treasury or any sub-Treasury or depository bank. Remittances for this purpose will be received by the Treasurer and Assistant Treasurers in the form of drafts on any bank or banker in Washington, New York, Boston, Philadelphia, Baltimore, Cincinnati, Chicago, St. Louis, New Orleans or San Francisco."

GEORGE H. PHILLIPS will probably be Capt. Hillman's successor as Inspector of Bolders here. His appointment has been recommended to the Secretary of the Treasury by the Board of Examiners. Mr. Phillips is at present superintendent of the Pacific Coast Steamship Co., and is a thoroughly experienced man,

Cutting Timber on Public Lands.

It May Be Done for Certain Purposes.

Commissioner Carter of the General Land Office, with the approval of Secretary Noble, has issued to registrars and receivers an important circular letter of instructions which shall govern in carrying into effect the sections of the General Land Act of March 3, 1891, relating to the cutting of timber from public lands. These sections only apply to the States of Colorado, Montana, Idaho, North Dakota, Wyoming and Nevada, the Territory of Utah and the District of Alaska.

The important features of the circular are as follows: "Settlers upon public lands, miners, farmers and other bona fide residents in either of the States, District or Territory named in this Act, who have not a sufficient supply of timber on their own claims or lands for firewood, fencing or building purposes, or for necessary use in developing the mineral or other natural resources of the lands owned or occupied by them, are permitted to procure timber from the public lands strictly for the purposes enumerated in this section, but not for the sale or disposal or use on other lands or by other persons; but this section shall not be construed to give the right to cut timber on any appropriated or reserved public lands, and the Secretary of the Interior reserves the right to prescribe and revoke such privileges.

"Persons, firms or corporations who desire to cut timber from the public lands for the purposes of merchandise, or for any other use whatsoever other than as defined in sections 2, 3 and 4 of these regulations, must first submit an application therefor to the Secretary of the Interior, designating the lands by sections, township and range, if surveyed, and if not surveyed describing the land by natural boundaries, and the estimated number of acres therein. They must also define the character of the land and the kinds of trees or timber growing thereon, giving an estimate as to the quantity of each kind, stating which particular kind or kinds they desire authority to cut or remove, and the specified purpose or purposes for which the timber or product thereof are required. The application must be sworn to and witnessed by not less than four reliable and responsible citizens of the State, District or Territory in which the land is situated, and who reside in the locality of the particular land described. The petitioner or petitioners should also submit with the application such evidence as can be procured to conclusively show that the preservation of trees or timber on the land described is not required for the public good, but that its use as lumber or other produce, and for the purposes named in the application, is a public necessity, and if deemed for the public interest the desired permission will be granted.

"In order that farmers who desire to have forests preserved in the interest of a water supply for irrigation, and all others having adverse interests, may have due notice of such application, the parties making application shall cause to be published, at least once a week for three consecutive weeks, in a newspaper of general circulation in the State, District or Territory, and also in a newspaper in the county, or, where there is more than one county, in each of the counties wherein the lands are situated, and a printed copy of the published notices must be submitted with the application, together with the affidavits of the publisher or foreman of each newspaper attached thereto, showing the same was successfully inserted the requisite number of times and the dates thereof.

"The cutting or removing of any timber from the public lands described in the application by or for the applicant, before his authority has been officially granted by the Secretary of the Interior, will render the party so offending liable to prosecution for trespass and subject his application to rejection.

"Sawmill owners, lumber-dealers and others, who in any manner cause or procure timber to be cut or removed from any public lands in violation of law, or these rules and regulations, whether directly or by men in their employ, or indirectly through contract or by purchase, are equally guilty of trespass with individuals who actually cut or remove such timber and are alike liable to criminal prosecution."

Breyfogle.

The *Chloride Belt* says: It is said that the men already at the Breyfogle mines take out enough gold from their placer claims to enable them to pay wages to new arrivals to work in their quartz claims.

By wagon road the Breyfogle mine is 200 miles from Candelaria. The road is a good one, water being within a day's journey in all cases excepting between Amagosa and Ash Meadows, a distance of 55 miles, where it is necessary to pack it.

Southward the star of Empire takes its way. Breyfogle continues to draw restless spirits from Candelaria and other adjacent towns.

Sheriff Boh Stewart came in from State Line to-day. He informs us that L. J. Hanohett returned from Breyfogle the early part of the week and is enthusiastic over the new discoveries. He will at once remove the Stewart mill, three miles from Lida, to the scene of the new discoveries. Mr. Hanohett will return to Breyfogle the coming week.

Now for the other side. Hank Melone and S. B. Fuller of Tule Canyon also returned from

Breyfogle. They report the new discoveries to have been grossly exaggerated, and declare that at present there is nothing there to induce the rush. However, as there is mineral all over the country, they concede that some of the numerous prospectors are liable to make important discoveries at any time.

Gas Treatment for Insects.

California can claim credit for the suggestion and practical development of many insecticides and insecticidal apparatus. Perhaps the most striking is the treatment of large trees with gases for the destruction of scale insects. This treatment is now being largely used for scales infesting citrus fruit trees in the southern part of the State. We have from time to time published information on this point and illustrated some of the devices employed for bringing the poisonous vapors directly to bear upon the scales. We give herewith a very complete arrangement for enclosing trees in tents in which the gas is generated—two tents being employed to save time, because while one tent is being filled with the gas the other one is adjusted upon another tree. The engravings are

Minerals in the Big Horn Mountains.

The opening of the Crow reservation, says the *Montana Mining Journal*, restores to the public domain all the mountainous land in the Big Horn mountains, west of the Big Horn river, and this will be open to the prospectors soon as the west boundary of the Crow reserve is surveyed and marked, as provided in the law. So far none of the precious metals have been found in the mountains, though there are tales and rumors of some rich gold leads on the north side of them. Gold has been found in placers and lodes on the head of Tongue river last year, and no doubt a number of people will visit that locality this spring as soon as the snow will permit them to prospect for the precious metals. These mountains have never been prospected in a thorough manner. In 1864, Bridger led a train, which was accompanied by a number of men who came to seek their fortunes in Montana, to Virginia City, and stopped in the Big Horn Basin, on the west side of the Big Horn mountains, several weeks to recruit, and while there, Mitch Bonyer, a famous scout, afterward killed with Custer, led a party of prospectors across the

A Virgin Field for Prospectors.

There have been no rich placer fields discovered since 1865. In the 15 years that intervened between the first excitement in California and the last excitement in Montana, Idaho and British Columbia, thousands of prospectors who had learned their sailing in the gold-fields of California used pick, shovel and pan on every creek and bar on the Pacific Coast, and the fact that no diggings of consequence have been discovered in late years is pretty good proof that their search was a close one, and that they did not run over the ground. Tradition is that old Mexico was thoroughly prospected for gold and silver quartz ages ago, the result of the prospecting being the discovery of mines that were worked for centuries. The prospecting must have been thorough, for, although visited by many of the most noted prospectors of America, no finds of importance have been announced of late years. What is true of Old Mexico is, in a great measure, becoming true of the United States. Although the mining industry in the Republic to the south shows no signs of exhaustion, it will be admitted by all observing men that the field for

did it the other night. He is an employee of the Ryan smelter, working on the night shift, and it is only through great presence of mind that he was not burned to death. By some mistake he lost his balance and started to fall headlong into an immense pot of molten metal. As he fell he caught the rim of the pot, and although he was immersed almost to his armpits, he drew himself out, and with almost superhuman effort threw himself into an adjoining pot filled with cold water. Some of his fellow-workmen saw him cast himself into the second pot, and rushing to his assistance, rescued him. His hands were badly burned, but otherwise he had hardly a scar on him. The secret of his escape was that he had on heavy woolen underwear and outer clothing, and before it had been burned through, Adams was in the pot of cold water.

Gum in Ramie Fiber.

The recent discussions of ramie-growing and fiber extraction have had allusions to the gum in the fiber as it is removed from the stem of the plant and the necessity of its removal. There has been inquiry as to the proportions of raw fiber to stem, of ungummed fiber to raw fiber, etc., in California grown and treated samples of ramie. Some assays of ramie have recently been made at the Experiment Station laboratory in Berkeley, concerning which we have secured from Prof. Hildard the following preliminary facts, which will no doubt be presented in more formal shape in some future Station publication.

The samples of ramie used in the investigation were (1) raw fiber decorticated by machine during the last Mechanics' Fair in this city; (2) a sample worked by hand for comparison at the University. The following are outline results of the assays:

Machine-made fiber from S. F. contained:	
Moisture (dried at 100° C.)	12.00 %
Gum	34.00 "
Ramie air dried and worked in Berkeley by hand:	
Moisture (dried at 100° C.)	11.17 %
Whole bark	21.20 "
Fiber (raw with gum)	15.90 "
Fiber (pure without gum)	11.00 "
Whole bark (air dried) contained:	
Cuticle	25.00 "
Decorticated fiber	75.00 "
Gum (contained in above)	41.50 "
Fiber decorticated by hand:	
Contained gum	30.80 "

The above data show that the estimate heretofore made of 15 per cent of raw fiber from the dry stalk is a conservative one; and the fact that the percentage of moisture in the stalks and in the raw fiber is practically the same, shows that the same rate will hold out in the drier air of the interior of the State, although, of course, both stalk and fiber will weigh several per cent less in absolute measure.

It is also seen that about 79 per cent of the entire stalk is recovered in the form of trash, available for return to the soil; to which will be added five or six per cent of offal, consisting of the outer skin (cuticle) of the bark and of gum mechanically detached in the process of decortication. The value of this offal as a return to the soil is now being investigated.

The two last columns give a good idea of the large proportion of gum contained in the outer coat of the stalk, being nearly 42 per cent in the "whole bark," and from 30 to 35 per cent in the "decorticated" fiber. The smaller percentage found in the sample treated at the University is doubtless due to the raw fiber having been worked (by hand) in the driest condition possible, while the machine worked in the damp air of San Francisco, renders the gum less brittle and therefore detaches less of it than will be the case in the dry air of the San Joaquin valley.

ASSAY OFFICE AND CHEMICAL LABORATORY.—After nearly 15 years' steady service in the position of chief of the ore-assay and analytical department in the house of Thomas Price & Co., Mr. J. T. Evans has severed his connection therewith and has opened an assay office and laboratory at rooms 46 and 47 Montgomery Block. Here Mr. Evans proposes to devote himself to the following lines of work: Assay of ores for gold and silver, lead, copper, iron, tin, zinc, mercury, antimony, etc. Analyses of ores, minerals, metals and their alloys, waters, soils, clays, lime, mortars and cements, fertilizers, coal, natural gas, tanning materials, alcoholic liquors, baking powders, carbonate of soda, borates, waste products, paints, oils, dyes, coloring matter, etc. He will make also analyses appertaining to medical chemistry, and examinations of drugs, chemicals and food, to ascertain their purity. Mr. Evans is a skillful and experienced man, and deserves a fair portion of the patronage of the interested public.

VERY RICH ROCK.—Sam Boston and his partner not long since pounded out in a hand-mortal a large candle box full of ore from their mine in Silver City, from which they extracted over \$1200 worth of gold. The residue was then thrown in an amalgamating pan to enrich lower grade ore.

A DEPOSIT OF \$150,000 has been made in Victoria, B. C., as the first payment of a total sum of \$1,500,000 offered for the purchase of the Silver King mine on Toad mountain, West Kootenai.

SIDE AND FRONT VIEWS OF APPARATUS USED IN THE GAS TREATMENT FOR KILLING SCALE INSECTS.

from the 1890 report of the State Board of Horticulture and represent the apparatus built by S. W. Preble of Tustin City, Orange Co., Cal., and is used in his orange grove. The measurements were taken on the spot by J. A. Shilling, and, in connection with the drawings, should convey a full idea of the construction of the device. The scale is $\frac{1}{2}$ inch to 1 foot. The apparatus, attended by two men, worked most perfectly in all its parts.

In the figures the lettering is thus explained: A. Wagon. B. Tents (2). C. Main yard. D. Mast. E. Crossbars (2). F. Ladder. G. Mast stays (6). H. Main yard truss (2). a. Trull boards (8), to bottom edge of tents. b. Guide lines (S), one-half inch diameter to trull boards, 30 feet each. c. Six-inch blocks (2), double sheave, for hoisting tents. d. Four-inch blocks (20), single sheave, for hoisting trull boards. e. Belaying pins (4), galvanized iron, to fasten ropes. f. Main ropes (2), three-quarters inch diameter, for hoisting tents, 190 feet each. g. Trull ropes (8), for hoisting slides of tents, one-half inch diameter, 120 feet each. h. Rope thimbles (32), one-half inch diameter, galvanized iron, for trull ropes of tents. i. Six-inch sheaves (2), brass, in main yard, for hoisting tents. k. Five-inch sheaves (6), brass, in main yard, for hoisting tents.

The process of generating the hydrocyanic gas to fill the tents to destroy the scale and the duration of exposure necessary to kill the insects, etc., has already been published in our columns.

WATCH FACTORY.—Articles of Incorporation of the San Jose Watch Company have been filed at San Jose with a capital of \$350,000. The company has bought the Olay Watch factory plant and will locate it at Alviso, Santa Clara county.

mountains, who panned the streams in the mountains as well as those which issue from them and run into the Little Big Horn and Big Horn rivers. While they found gold everywhere, in no place was the dirt rich enough to induce the party to encounter the danger from the Indians, which at that time was very great, by remaining to work the richer ground.

The greater portion of these mountains being on the Crow reservation, has kept them from being prospected in recent years. The people, or, rather, a few of them, along Tongue river have done some prospecting, and some lodes have been found, but they have never been systematically worked, and their value is not known. The difficulty of prospecting these mountains is great. They are abrupt, and the walls of nearly all the streams form box canyons, the larger of which are hundreds, and in some instances, thousands of feet deep, and which can only be entered at a few places. One of the greatest of these is the Black canyon, which is some 25 miles long and empties into the Big Horn river, some 10 miles south of the mouth of the Big Horn canyon. To this there are but two or three entrances, and these very rough and difficult. This canyon follows the line between Montana and Wyoming, and some time will be sought by tourists as one of the celebrated places in the mountains. Now that gold has been found in paying quantities in these mountains, and some 60 miles of them opened to the prospector, we shall be surprised if some good camps are not located in them in the next five years.

The supervisors have refused to grant the California Electric Improvement Co. a franchise for the erection of poles, wires, etc., in this city, the object being to prevent any more poles from being put up.

the surface prospector is becoming less in extent each year.

Nevada, the alma mater of the quartz prospector, has been as thoroughly prospected for quartz as California, the alma mater of the placer prospector, has been for placer ground, and a rich quartz find in the one would be as surprising as a rich placer find in the other. Colorado is fast becoming like Nevada. Montana, Wyoming, Utah, New Mexico and Arizona are no longer virgin fields. While Idaho and Washington have still small areas unprospected, the veteran prospector does not take kindly to the general mineral character of the latter, and hopes for little from the former.

There is but one region on the Pacific Coast left untrod by these pioneers of an industry that has done so much to uphold an empire in the West. That region extends from the international boundary line north to the 60th degree of latitude—a distance of fully 700 miles—with a breadth of from 200 to 300 miles. That this region remains virgin is because of the foolish saying, oft repeated, that there is no mineral north of the international boundary line, taken in connection with the idea that the laws of British Columbia are illiberal and unfair. The discovery of vast mineral wealth in the Kootenay Lake country disproves the foolish saying, and the laws of British Columbia need only to be examined to prove that they are not only illiberal to the prospector but fair and just to all law-abiding people. In no country on earth is life and property more safe than in British Columbia; and no people are more tolerant on political questions.—*British Columbia Miner.*

IMMERSED IN MOLTEN METAL.—But few men, says the *Tacoma Globe* have ever fallen into a riot of molten metal and escaped with a few trifling burns, yet John Adams of Tacoma

MINING SUMMARY.

The following is mostly condensed from journals published in this interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Cor. Amador Ledger May 9: Since my last, operations at the North Star have come to a sudden standstill. How long the suspension will be is hard to say. The developments have been discouraging for some time, but the stockholders have kept up the assessments in the face of all discouragements, and deserve great credit for their pluck and enterprise, for they are mostly poor men. The general opinion among those interested is that they should drift in some other direction, and perhaps sink, as there is absolutely nothing in sight to justify going any farther. As the bond of the property expires in June, it was not considered advisable to undertake further development without first securing an extension of the bond. After a number of propositions were discussed, one seemed to strike the directors favorably, namely, that the owners were willing to grant an extension of the bond for five years, on condition that in the event of striking ore one-third of the gross proceeds shall be applied to the purchase price until the entire price, \$27,000 is paid. Papers were drawn up to this effect, but after a more mature consideration of the matter, a majority of the directors refused to sign the agreement, claiming that it would be more just to allow the net proceeds to go toward the purchase price. This the owners refused. So the matter stands at present. There will be another meeting of the directors in June, when all differences may be adjusted and operations resumed. The lessees of the Lincoln, who became discouraged on account of the ground caving in consequence of the heavy rains, have re-organized, and started to work again with renewed energy. They are busy fixing up the mill, and in a few days the stamps will be ready to drop. They have found a new stratum of ledge matter, which prospects well, and feel confident of a good run this summer. R. C. Downs and company are running a tunnel into their gravel claim at Humbug hill, and expect to strike pay gravel at an early date. At the Mahoney work is progressing as rapidly as possible. The rock that lay on the dump has been all run through the mill, and carpenters are busy repairing, and putting everything in good order. Miners are at work repairing the tunnel leading to where they expect to get their pay dirt. In another week I hope to report the mill in activity.

NORTH STAR.—Amador Dispatch, May 9: The North Star mine company has ceased operations for good. The original shareholders and the improvement could not come to terms about the extension of time. They have already begun to tear up the track iron that is in the drifts and tunnels; all the improvements will be moved as soon as possible. The closing of this mine throws quite a number of men out of employment.

Calaveras.

HALLOCK.—Mt. Echo, May 7: A free gold or battery test of ore taken from the Pioneer, or Hallock mine, situated near this town, was recently made, the yield of which was \$39.38 per ton. Tests of the sulphurets have also been made which have proved highly satisfactory to the company. The new 20-stamp mill, now in course of construction on this mine, will soon be completed.

Contra Costa.

THE LIME QUARRY.—Contra Costa Gazette, May 9: In the earlier days, that is to say, some 30 years ago, the lime quarry near the present site of Concord was successfully worked by a pioneer resident, Frank Such, and a considerable quantity of lime was burned by him and shipped by way of the creek to San Francisco. He was succeeded by Mr. Gibson, and after him if our memory is correct a party named Allen continued the business for a while. But, as was understood at that time, it competed too sharply with the Santa Cruz product, and the quarry was leased in the interest of the latter and closed down. The term of the lease expired some years ago, but no one has seemed disposed to go into the business of lime burning. Some three or four months ago a gentleman appeared in Martinez and made inquiries for lime rock. He was cited to the old lime quarry, and stated his intention of visiting the spot. Nothing was heard of him afterward, but now that Mr. Wm. Cavanagh has a contract to deliver a large quantity of rock from this quarry to the Selby Smelting Works, this may be the outcome of his visit. The transportation facilities now make it the most convenient point from which to obtain the needed supply, and after the long rest we are glad to note the resumption of operations.

El Dorado.

MILLING ORE.—Georgetown Gazette, May 9: Armstrong & Ritchie have evidently got the boss mine of milling ore. They have been running in on their large ledge steadily for the past month, and every foot of progress has shown a fine grade of milling ore, and now so well satisfied are they with the permanency and extent of the ore that they have determined to equip the mine with a good mill and work it themselves. The mine is not for sale, as the parties command sufficient capital. They have about 400 feet of backs from Dark Canyon where they have started the tunnel. They have an abundance of timber and can run the works at a small cost. All who have seen their developments, say that they have got a big thing.

Inyo.

BIG PINE.—Inyo Index, May 9: The little hamlet has other assurances of future prosperity and greatness from the assurance of the immediate success of a number of mining projects in this vicinity. Mr. John Quillan, who has been associated with Andy Fife of Sylvania notoriety in the development of the mineral resources of Inyo for some time, accompanied by Mr. J. C. Webber of Bodie, is off for the Montezuma mine, intending to sack and ship several carloads of ore from this celebrated property. On our side of the river mining industries at Fish Springs are looking up. The old arrastras are running in full blast, and Mr. Dan Trussell hopes to have his new one soon under the influence of a mountain stream.

Nevada.

W. Y. O. D. MINE.—Grass Valley Union, May 10: The W. Y. O. D. mine will declare a dividend

(No. 3) for the current month, amounting to \$1500. The company has just had a return from the Selby Smelting Works of a lot of sulphurets, which gave a net result of \$250 per ton, the gross product being over \$300 per ton. Preparations for building the company's new ten-stamp mill is making progress. The machinery and a portion of the lumber is on the ground. The building of the mill and other contemplated improvements on the surface will require some months for completion.

CALIFORNIA.—Grass Valley Union, May 7: Some fine looking ore has been taken out of the shaft of the California mine, on Deadman's Flat, since the pumping has been going on, and the same quality of ore shows in the levels that have been drained. The water in the shaft has been lowered 200 feet, and the water will soon all be out. It is the intention then to open up the lower level, and have a test crushing of the quartz. From the appearance of the vein as already exposed it looks as if it would give good milling returns.

NEW ENTERPRISE.—Tidings, May 7: Gold Flat, in Nevada City district, is shortly to be the scene of mining operations that are confidently expected to develop a valuable property. The promoters of the enterprise are well-known Grass Valleyans, including John Glasson, John Skewes of the North Banner mine, T. J. Michell, John M. Thomas and others. Articles of incorporation will be filed in a few days. These gentlemen have bonded four claims or ledges, all of which can be worked through one shaft. These claims are the Mohican, Bruce Lee, Gold Flat and Potosi; and the Bruce Lee shaft, between 200 and 250 feet in depth, has been selected on which to erect the plant, which will be economically operated by water-power. All of these ledges have paid good wages to water level and under the most indifferent—not to use a stronger word—management. The Bruce Lee and Potosi are north and south ledges, pitching east, while the Mohican and Gold Flat are east and west ledges, pitching south. The advantages for working all four through a central shaft will readily be appreciated by mining men. The country rock is slate, as in the Grass Valley district. The capital stock of the new company will be 100,000 shares, of which the old company (owner or owners of the claims named) retain 49,000 and the new company 51,000 shares. It is proposed to place 30,000 shares on the market at 25 cents a share, to be paid in three installments—two of 10 cents and one of 5 cents per share. The capital thus realized will be devoted to the erection of a plant and the development of the property.

CENTRAL NORTH STAR CO.—Grass Valley Union, May 6: The Central North Star Mining Co., which was recently incorporated, whose location is on the south portion of New York Hill, has commenced preparations to open the mine. The first work that will be done will be the cleaning out of the adit level, which is 400 feet in length, the mouth of which is on Wolf creek, a short distance above the Omaha mill. This level strikes the vein which is ten inches in width, at a vertical depth of 200 feet below the surface. It is the intention when the level is put in shape to erect machinery on the surface and sink a shaft on the vein connecting with the end of the level. This vein has given good prospects, and the new company intends to open up the mine in good shape. James Bennallack has been appointed superintendent.

GOLD POINT MINE.—There is a probability of the Gold Point mine soon being started up to conduct operations regularly. The vein is large, from two to two and one-half feet, and can be cheaply worked. The last crushing from the mine gave a yield of \$14 to the ton.

Placer.

THE HOGSBACK CLOSED.—Placer Republican, May 6: The Hogsback mine has closed down temporarily, probably for a year. The cause attributed is that the company will reorganize, and the absence of some of the members from Paris necessitates such a long delay. The gravel in the channel is very rich, but its paucity in quantity has caused the yield of gold so far to be comparatively small. The Red Point drift mine some ten miles farther down the divide is paying satisfactory dividends monthly. The company has over 27,000 linear feet of channel which insures dividends for many years to come. The old Hidden Treasure is still on the list as a good paying mine. A large force of men is constantly employed drifting out the vast deposit of white quartz gravel. Underlying all this section of the divide are many "ancient river beds, but only a few have been discovered and developed. Michigan Bluff has been rather dull for some time past, but a new era of prosperity is about to dawn, for the Deadwood district only a few miles above here is getting to be a lively camp. Outside capital is being invested and the mines are looking prosperous. At the Paragon and May Flower mines active work is being prosecuted and regular dividends are a result. Other properties in their vicinity are being worked, mostly for the purpose of development.

Shasta.

A GOOD MINE.—Redding Free Press, May 9: The Gladstone mine, formerly owned by Osborne, Morrell & Cummings, and which was sold to the present owners, has turned out to be one of the best paying mines in the county. Under the new management the mine has been opened up in a systematic manner. Good and adequate machinery has been put in and every labor-saving device known to mining has been made use of. Not long since, on a run of 21 days, \$14,000 was shipped to S. F., and last week, after a run of 30 days, \$28,000 was cleaned up—almost \$9000 per day. And still there is an abundance of good ore on hand. The French Gulch district, in which the Gladstone is located, has been very productive of gold in the past, and the future seems bright and promising.

Sierra.

A PROSPECT.—Mountain Messenger, May 9: The company sinking the shaft opposite the mouth of "Nigger" Canyon reached the bedrock at a depth of 94 feet, and found a prospect. The shaft was sunk not to work through, but simply to test the ground for gold and depth. An exploring tunnel will now be pushed off at the bottom of the shaft, and if developments are satisfactory, a tunnel will be run to tap the channel at its lower end. It is quite evident that the South Fork once ran in the channel where the shaft is sunk, and that an immense land-slide came from the hill to the North, forcing the river out of its then bed and forming what is now Fournier's Flat.

EXTENSION.—Superintendent Meikle, of the B. M. Extension mine, is expediting the work of getting ready to take out and wash gravel, as much as possible. He has only been able to find room for a few men in addition to the force he has been employing. Among the first things to be done is the building of a reservoir to catch the water flowing from the tunnel, the building of a large dump, putting the blower in place, etc. It will be some little time before lumber can be got as it will have to be specially cut. At present a team can get within about half a mile of the tunnel mouth. Two of the upraises in the tunnel have been connected by a drift, primarily to secure a circulation of air, and for the purpose of prospecting the gravel, which was found to contain good pay.

STRUCK RICH GRAVEL.—Maple Grove Mining Co. has struck it rich. This claim has been prospected through a shaft, and the gravel contained \$10 a carload. Three hundred feet of channel of the finest looking gravel that has been seen since the old blue lead days. This is supposed to be the deep lava channel which was crossed by the B. M. Ex. old tunnel just below the incline. The company is about to start a tunnel to tap the channel. This claim is located about two miles southeast of Forest City. This find together with the opening of the Extension, is liable to bring Forest City to the front again. The above is the first intimation we have had that any prospecting was being done for this channel, which is none other than the lower channel worked by the Ruby Co. If the Maple Grove Co. have found this channel, and have any great amount of ground, it has a good thing. The Extension Co. owns nearly 3000 feet of this channel next below the Ruby ground; the South Fork Co. owns probably as much more of it, adjoining the extension ground, on the south; and it has long been our opinion that this channel crosses a portion of the Mammoth Spring Co.'s ground. If the southern end of this channel has been discovered, we do not see anything to prevent the owners having a very valuable property, and one that can be economically worked.

Siskiyou.

COAL.—Yreka Journal May 6: Henry Harris brought to town last Friday some more samples of superior coal from Willow Creek, the coal lead improving in quality, the more it is developed. The mine has been opened to a depth of over 70 feet, disclosing a bed from four to five feet thick, with, considerable water, to require the steady use of pump. This coal discovery in Siskiyou is destined to prove a source of great wealth to the owners, and will induce prospects in various other sections, where croppings of shale and coal are visible.

GRAVEL.—Lee, Lash & Co., have their new machinery in position for hoisting blue gravel at their Greenhorn claim, also the steam pump, and are now getting out the pay gravel to better advantage, the only drawback being a slack up in the water supply for operating the sluices to best advantage. The claim was all pumped out again Saturday and work was resumed in the drifts on Sunday night, with day and night shifts now working steadily.

A BIG STRIKE.—For a number of years, miners prospecting on the north fork of Hiyou gulch, have noticed a large ledge of quartz, which cropped out of the surface of the ground. They generally tested it and pronounced it worthless, consequently it has remained unlocated until recently, when two of our most enterprising men, H. C. Chester and J. E. Williams placed their notice of location upon it, and commenced work. Mr. Williams, who is a miner of no little experience, conceived the idea of tapping the ledge about 20 feet under ground by running an under-cut. After two months' incessant toil, he struck the ledge on the 27th inst., and to all appearances, struck it rich as well, for the quartz, which prospected so little on the surface, prospects at from \$15 to \$25 per ton where it has been tapped. The ledge is four feet wide and easily worked, therefore if it will pay \$10 per ton on an average, it will prove to be the richest bonanza ever yet discovered in Siskiyou county.

Trinity.

THE YELLOWSTONE.—Trinity Journal, May 9: T. J. Houghton, Superintendent of the Yellowstone mine, was in town this week and reports everything at the mine running smoothly and the output of bullion very satisfactory. Mr. Houghton is a thorough mining man and has made a success of every enterprise he has conducted. The Yellowstone, under his supervision, has been made a success and now ranks among the best quartz mines of the county, giving employment to a large force of men.

Tuolumne.

SUGAR PINE DISTRICT.—Cor. Tuolumne Independent, May 9: In last week's issue of your valuable paper I noticed an article on the Sugar Pine Mining district. For information to old-timers and present Tuolumneites, I will give you some items that will astonish a good many as to what has been taken out of this rich mining district, and will show that it still has a good outlook for one mile square. The Excelsior mine had the largest receipts, as far as can be learned, and are as follows: Gold shipped to Bank of California—W. Ralston's receipts, \$128,921; Wells, Fargo & Co., \$215,344; Sleeper & Co., \$80,000; total, \$424,265. From the Mount Vernon it is estimated that over \$50,000, and from the Green mine over \$44,000 were taken out. The Pacholke & Jasper mine is now bonded for \$30,000. The First Extension Green mine is looking well. The owner is sinking a shaft on the vein, which is looking very encouraging. Work on the Lillie Prouse mine will soon commence. As soon as water can be brought on the Jim Claim mine it will undoubtedly show up well, as the rock now prospects from \$80 per ton up, in free gold. Then comes the largest mine in Sugar Pine district, situated east of the Green mine, and owned by Dooly & Ryan. It is a sulphuret vein, ranging in size from 6 to 12 feet in thickness, and crops out on the surface in places, four and five feet high. It was originally owned and worked by an old prospector, Fred Greiner, Sr., who took out considerable gold, down near the river, but for some reason unknown to the writer, abandoned it years ago. So you see that for a mile square, Sugar Pine Mining district shows up as well as any.

THE KELTZ MINE.—Union Democrat, May 9: The Keltz mine situated northeast of Sonora, about 12 miles, has been sold to an English Co. It was bonded to the company and has been under development by them for several months. They are

well satisfied with the results and the sale has been consummated. Mr. Leachman lately arrived in S. F. from London. He negotiated the sale in England. The mine has a good 10-stamp water mill on it. The capacity of the mill will soon be increased by additional stamps. The ores of this mine can be mined or milled at small cost per ton. The ore shoots are reached by tunnel and all the machinery is operated by water power.

Yuba.

MINING AT SMARTSVILLE.—Grass Valley Union, May 10: Mr. Turner is getting things in shape for an early commencement of work in the Golden Gate mine at Smartsville. A considerable force of men will be employed when the drifts are properly opened.

NEVADA.

Washoe District.

YELLOW JACKET.—Are doing extensive prospecting work throughout the mine.

ALTA.—Steam is up and have resumed exploring work.

BELCHER.—The south drift from No. 2 east crosscut, 200 level, is out a total distance of 230 feet, face in quartz and porphyry, containing occasional bunches of ore. The north drift from the main west crosscut from the shaft, 300 level, is out 66 feet; face is in low-grade quartz and porphyry. The east crosscut from the south lateral drift on the 1500 level is out a total distance of 87 feet; the face is in hard porphyry.

CROWN POINT.—Have stopped the south drift on the 300, eleventh floor, and started a north drift from this stop on the same floor; face is in low-grade quartz. The 1000 level east crosscut is out 57 feet, having been extended 16 feet during the week; the face is in porphyry, with streaks of low-grade quartz through it.

CHALLENGE CON.—The joint Confidence and Challenge west crosscut from the north drift on the 300 level is being repaired. The joint Confidence and Challenge east crosscut on the 600 level is out 27 feet, 4 feet having been made during the week; the face shows clay. This crosscut has been stopped for the present. The joint Confidence and Challenge west crosscut, same level, is out 10 feet, having been commenced during the week; face shows quartz having no value. The joint Confidence and Challenge north drift on 1100 level is in 211 feet, 22 feet having been made during the week; the face being in porphyry. The joint Yellow Jacket, Confidence and Challenge north drift on the 200 level is in 720 feet, 11 feet having been made during the week; face shows quartz having no value. The joint Challenge and Imperial west crosscut, 300 level, is out 90 feet, 14 feet having been made during the week; face shows quartz having no value.

CON. IMPERIAL.—We are still following up and taking out small streaks of ore on the upper levels and prospecting in and around the old stopes, where we find some fillings and bunches of ore of fair grade, which is being shipped to the Vivian mill for reduction.

SEG. BELCHER.—On the 600 level the west crosscut from the south lateral drift reported as having been started last week, is out a total distance of 26 feet. The face is in soft porphyry.

KENTUCK.—Have stopped the west crosscut from the south drift two floors above the 1000 level, and started a raise from the south drift. The top is in low-grade quartz. Have raised 9 feet from the 1000 north crosscut, and are up a total distance of 37 feet. The top is in low-grade quartz. Have advanced the drift from the top of the raise in the west ledge 9 feet. The face is in quartz assaying from \$6 to \$12 a ton.

JUSTICE.—No work was done in the south winze on the 400 level during the week, as it is the intention to raise from the 622 level to connect with it. The north drift on the 822 level is out 663 feet. The face is in ore of fair quality. The upraise 300 feet south of the switch on the 822 level is progressing well, with favorable prospects.

CHOLLAR.—The south lateral drift from the north line, 1400 level, is out 107 feet; face in hard porphyry. Joint east crosscut on the north line, 1400 level, is out 105 feet; face in porphyry.

POTOST.—The south lateral drift from the Chollar incline, 1100 level, is out 120 feet; face in porphyry. South lateral drift from the winze station, 1300 level, is out 120 feet; face in quartz and porphyry. The winze is down 51 feet below the 1400 level; the bottom is in porphyry.

NEW YORK.—North lateral drift, 650 level, is out north of shaft 186 feet; face in porphyry. North lateral drift, 1100 level, is out north of shaft 468 feet; face in quartz yielding low assays.

ALPHA AND EXCHEQUER.—But little work has been done in the above mines the past week, owing to repairs to the shaft.

CON. VIRGINIA AND CALIFORNIA.—Virginia Chronicle, May 8: Exploratory work on the 1100 level of Con. Cal. & Va. was resumed yesterday. It is intended to prospect the ground thoroughly to the east and west of the south drift, where the upward extension of the ore vein from the 1200 level was found, for it is believed that there are some outlying bodies of ore in the vicinity. The prospects of the west side are especially good. The main south drift from the old Con. Cal. & Va. shaft has been carefully timbered, the requisite ventilating machinery has been put in, and everything is now in readiness for an energetic campaign in the big block of ground never before opened. Other parts of the mine are looking well. Ore shipments to the Morgan mill will begin at the close of the week. The Eureka mill is now being cleaned up, and a large hullion shipment to close the April account will soon be made. As two mills will soon be running regularly on Con. Cal. & Va. ore, the hullion product of the mine will be more than double what it has been.

SILVER HILL.—Northwest drift, 50-foot level, is out from the shaft 160 feet; face in porphyry. North crosscut, 160 level, is out from the winze 730 feet; face in hard porphyry.

WARD COMBINATION SHAFT.—The east drift from the 1800 station is out 963 feet; face in porphyry.

SAVAGE.—We have hoisted 426 cars of ore from the 500, 750, 800, 900, 950 and 1000 levels and from the north and south drifts from the winze below the 1300 level. Shipped to the Mexican mill 5364 tons and milled 530 tons; average battery assay, \$17.50. We have hullion on hand amounting to

\$29,566. From the east intermediate drift below the 1300 level we are sinking a winze which is now down 23 feet. This winze will connect with the 1300 level north drift, which will improve the ventilation and enable us to prospect this section of the mines. On the 1400 level we have drifted north 29 feet on the ore, which continues to improve, and is being saved for pay.

HALE & NORCROSS.—On the 1400 level No. 4 west crosscut near our north boundary was advanced 10 feet; total length, 225 feet; face is in porphyry. The winze from the end of No. 3 east crosscut is down 60 feet; the bottom is in quartz. We have cut out a station and started an upraise on the 900 level, about 80 feet south of our north boundary line for the purpose of prospecting the ledge in that section of the mine. The main incline is being repaired and retimbered below the 1300 level, to enable us to construct a station and chutes. Have men on repairs in the main shaft and on different levels wherever necessary.

UTAH.—725 level engine station at the top of winze has been completed, and we are now putting in a hoist engine. A chute will be cut out at the top of the winze for the incline car to dump into. It will be completed in four days, and sinking in the winze will be resumed.

BEST & BELCHER.—1000 level: Cleaned and repaired 60 feet of northeast drift during the week. 1100 level: The northeast drift has been advanced 24 feet through porphyry and stringers of quartz; total length, 149 feet. Have cleaned and repaired west crosscut No. 1, 42 feet.

GOULD & CURRY.—200 level: Resumed work in the north drift and extended same 20 feet; total, 185 feet. Sunk winze No. 2, 40 feet east of winze No. 1, 30 feet through ore of a fair quality. Extracted during the week 106 cars of ore. Received from ore milled at Nevada mill \$11,406.03.

ANDES.—On the 420 level east crosscut from south drift has been advanced 24 feet during the past week; formation, vein porphyry. East crosscut from the north drift on the 420 level was extended during the week 25 feet; formation, quartz and clay.

Tuscarora District.

DEL MONTE.—*Times-Review*, May 8: Joint crosscut west has been advanced 25 feet. Joint raise from this crosscut has been started.

NEVADA QUEEN.—South drift from the east crosscut, fourth level has been run 15 feet in vein giving low assays.

COMMONWEALTH.—Fourth level: North drift from the east crosscut has been advanced 30 feet in the vein, showing quartz and spar, assays \$3 to \$15 per ton. East crosscut has been extended 24 feet, still cutting small seams but nothing of value. Have started to extract ore from 100-foot level.

BELLE ISLE.—The prospecting winze from the intermediate crosscut from No. 1 chute, 350-foot level, has been extended 8 feet, the ore continues of fair width and high grade. South intermediate drift, same place, extended 5 feet. East crosscut from top of No. 2 chute extended 18 feet. Work has been resumed in the west crosscut on the 350 foot level, to tap the ore showing in the prospect winze; progress 4 feet.

NORTH BELLE ISLE.—South drift from east crosscut, 400-foot level, extended 21 feet, total 41 feet. The face continues to show several strata of good ore; have started a stope over this drift, showing some good ore. Have broken 7 cars of first class and 78 cars of second class ore. The stopes from the north intermediate from No. 4 chute, 600 level, continue to yield high grade ore.

NORTH COMMONWEALTH.—First level: There is very little change in the stopes, the ore extracted and going to the mill, battery assay \$243 per ton. Union mill started crushing on the fourth instant (Monday). Battery assay \$243 per ton. Have crushed about 100 tons.

ALASKA.

PLACER MINES.—Juneau *Mining Record*, April 26: Work on the Silver Bow Basin Mining Co.'s property is progressing as rapidly as possible and by the time snow disappears everything will be in complete readiness for operations on an extensive scale. At a depth of 60 feet gravel was struck which prospects far beyond the most sanguine expectations of those familiar with Basin properties and it is now thought by those who are in a position to know that the tunnel will not tap the Basin at a sufficient depth to work the gravel at bedrock. This company has expended a large amount of money in opening this property and the work has been executed in a substantial and first-class manner and will stand as a monument of thorough and practical workmanship to Mr. Joseph Farnworth, the superintendent. The striking of good pay gravel at such a depth is recorded by the *Mining Record* with a great degree of satisfaction and will set at naught the communications published in the *New York Engineering and Mining Journal*, and written by irresponsible amateur mining men, so-called, whose only aim in life appear to be to bring the industries of the community wherein they live into disrepute in order that they may gain a little cheap notoriety. However, the time is not far distant when the merits of this property, which no one conscientiously questions, will be made known to the world. During the week a party of miners returned from the placer mines which are being opened in the Shuck district by a syndicate of gentlemen with Mr. John A. Bernhardt as promoter. These were the first placer mines worked in Alaska and at one time comprised a flourishing little camp but were abandoned on account of reported rich strikes in other sections of the territory, and also on account of the expense attached to a thorough and practical working of the same. The placer ground lies in two basins known as the upper and lower basin. The lower basin is in close proximity to the beach with a ridge separating it from the bay. In order to tap this basin at a depth of 65 feet required the driving of a tunnel for a distance of 700 feet. This tunnel is 7x7 feet with a fall of 4 inches in 12 feet and is located about 18 feet above high water. For the working of this property nature has furnished a bountiful supply of water which has been gathered up in ditches and flumes which lead from what is known as Spruce creek, at a point about 400 feet above the surface of the gravel deposit. This basin contains about 60 acres and embraces three claims of 1500 feet in length and 600 each in width. The upper basin is about 1000 feet above high water mark and contains about 20 acres. This basin is tapped by a small

tunnel about 100 feet in length, and through which a flume 28 inches in width runs.

ARIZONA.

NOTES.—Prescott *Courier*, May 9: Tip Top district miners are now shipping pretty plenty of ore to El Paso, Texas. Supplies are leaving Prescott for Bradshaw district, where the Crowned King mill is doing better work than ever before. The Tiger mine is looking fine. Mill will be started very soon. There are three mills running in Hassayampa district, the Senator, the one in Maple gulch, and Harlan's. All crushing gold rock. Aztlan mill, in same district, will soon be going. Turkey creek mines are sending in ore that goes from \$200 to \$800 a ton. More men are to be put into the Hackberry, Big Bug district. United Verde mines and smelters are behaving admirably. Many men say the district is the best in the mountains. The Catocin mine is producing good ore. It has paid from the grass roots.

CONGRESS.—F. M. Murphy, superintendent, and Mr. Church, foreman, arrived from the mine yesterday. Good ore is overflowing every bin and thing in and around the mine. Some of the ore of the Congress mine is said to contain 17 ounces of gold to the ton. The vein is strong at a depth of over 700 feet. Mr. Henderson of Walker district tells us that Mr. Ritchie, late of Colorado, is making the Dixie company's Wiswell mill do good work. He runs the mill steadily on free gold rock. B. A. Taylor, superintendent of the Quartz Mountain, and John McKinnin, the foreman, tell us that at a depth of 200 feet the mine is looking well. Plenty of good ore in sight. O. F. Place and N. C. Shelds, of the Crowned King, are in Prescott. Mill has been doing good work. Several hars of gold were recently sent East from the mill. Joe Howell and other miners are off for the Hillside district to take out ore and ship it.

RICH STRIKE.—Mohave *Miner*, May 9: Since the water has been pumped out prospecting has been commenced on the 150-foot level of the C. O. D. mine, and an important strike of rich ore has resulted. A portion of the hanging wall has caved off in one of the drifts, owing to the ground becoming softened by the water covering it, and exposed two streaks of ore averaging about eight inches each in width. The mine has never been thoroughly prospected and this unexpected strike will give a new impetus to the work of development. The mine has been a great producer, and is now in the hands of energetic young men who will not let a temporary pinching out of the ore deter them from the ultimate point in view—the thorough prospecting of their property.

COLORADO.

RICHER THAN EVER.—*Aspen Times*, May 7: The latest rich strike of ore has just been made in the famous Aspen mine. Stephanite in ton lots has been struck in the sixth level. Several tons of this rich ore have been extracted that run from 5000 to 10,000 ounces per ton. Dr. Paul, manager of the Aspen, has promised a 200-pound piece to be placed on exhibition at the Mineral Palace to-morrow, where people can see what richness is in store for them in the deep workings of the great mother contact.

THE HOLDEN WORKS.—Ed R. Holden, of the Holden livery works, is in the city and stated to a *Times* representative yesterday that his company would commence huying low-grade ores in July and that all the contracts had been let to have the works completed to a 120-ton capacity in the latter part of August, and that the capacity would be increased as fast as a demand was felt. This will be a great boon to Aspen and the proposition can be enlarged to 500 tons a day.

DAKOTA.

REDUCTION OF TIN ORE.—*Lincoln Journal*, May 7: People who scoff at the probability of seeing American tinware made from ore from the Black Hills will be a little discouraged to know that Mr. F. C. Sholes, of this city, has received a letter from General Manager Wicker, of the Harney Peak Company, giving a full account of the preparations that are progressing rapidly for beginning the reduction of ores on a large scale. Orders are out for all the machinery needed and it will not be long before the hock tin from these mines will be in use in half a dozen American factories. The facts about the Harney Peak mines have been rather slow in coming out, but it has nevertheless been known in Lincoln for a couple of years that the widely advertised failure of the first attempt to smelt these ores was not a failure at all, but a shrewd device of the London owners of the mine to gobble all the desirable mines in the vicinity at their own prices. Now they have bought up all the property that can be had, and are ready to demonstrate that they have one of the most valuable tin mining properties in the world.

BEAT THE RECORD.—*Deadwood Pioneer*, May 8: The cleanup of the Deadwood chlorination works for April went east Sunday, and for the number of days run, beats the record. The total number of days run was eighteen, and the value of the cleanup a little over \$14,000. The last six days run netted \$7,800.

IDAHO.

CUMBERLAND.—*Avalanche*, May 2: The Cumberland mine, on War Eagle mountain, owned and worked by Mr. Jas. Shaw, is making a better showing than ever before. It is a vein running parallel with and about 100 feet west of the once celebrated Golden Chariot and carrying ore very similar in character, but the bullion running slightly higher in value per ounce. Messrs. Shaw and Kennedy are now stopping ore from a chute found in the tunnel and have out a big crushing which they will have milled as soon as the road to the mine can be opened. The rock now out is estimated to be worth about \$200 per ton. It is rumored that this mine will change hands in a few days, as parties now hold an option on it at figures which justify them in closing a trade.

STORMY HILL.—Orders have been received from the owners to start work again on the Stormy Hill mines. The foreman, Simon Harris, has again got up steam at the hoist and begun taking out ore. The outlook at the mine when they shut down in

the winter was so very good that much surprise was expressed at work being stopped, but timbers could not be procured and other disadvantages under which work was done, probably justified their stop. As the shaft went through about 60 feet of high-grade ore, when they now begin stoping we expect to hear of good results. It promises to be a good producer.

SEAFOAM DISTRICT.—*Ketchum Keystone*, May 9: The *Keystone* was favored by a letter this week from Johnny Foster, who left here last fall to winter at Seafoam and do development work on mines there owned by himself and James Judge. He writes that he has taken out eight tons of first-class ore that will go from 200 to 400 ounces of silver per ton, and has about six tons more in sight. He has also made a location which he is sanguine will prove very valuable, as it is favorably located and opens out with highly flattering surface prospects. A rich strike was made in the Blackhawk mine last week. Mr. Foster, with the help of one man, John Honan, has run 100 feet of tunnel, sunk a shaft 30 feet, and run a stope 40 feet in good ore from ten inches to two feet thick, all in less than five months, which we regard as pretty good work for two men.

DE LAMAR.—*Vulgar*, May 5: The new manager, in assuming control of the great De Lamar mining property, has not, as some feared he would do, made any radical changes in the employees. Naturally enough, he has selected chiefs of some of the departments from among men whom he has personally known before coming here, and each of these have made some few changes among those working under them, but of the old men very few have been let out. Mr. William Rickenburg has been placed in charge of the mill. He is an experienced amalgamator, whom Captain Plumer has formerly employed in Montana. Mr. Thomas H. Oxnam, who has also for several years past been employed by Captain Plumer, has been appointed foreman of the mines. Some few of the old employees quit work on the 1st inst. when the changes were made, some to go prospecting or to work mining claims, and the places of these have been filled by new men; and in a very few instances men have been let out. Mr. Robert McAfee, who has been running the tramway from the time it was completed, has been put in general charge of the machinery at the mines and mill. Mr. Wm. Houtz, as formerly, remains in charge of the carpenter and construction work.

FLINT.—The experimental work done at the Flint mill with concentrators last fall, was sufficiently satisfactory to warrant its continuance. Mr. Leech has ordered that the mill be started up again at once, and will add ten more stamps and more concentrators to double the capacity. Miners will in a few days be put to work on the Last Chance mine, which, it is expected, will be able to supply the mill with better rock than that worked last fall.

DISTRICTS TRIBUTARY TO HAILEY.—*Wood River Times*, May 6: Pat Hannigan is shipping a ten ton lot of ore from the Mountain View. The Red Elephant will ship ore as soon as the road from the mine to Crov gulch is open, which will be in a few days. All the leasers on the Jay Gould are taking out ore. The boys have done well during the past winter. This mine has been worked two years on a lease, during which time it has paid continuously. It was originally opened up and operated by Warren Hussey, the well-known banker, who built a concentrator on the property in 1883, and a week or two after the completion of his plant shut down the mine and works, having no ore in sight. This is a notable instance of the folly of gouging out an ore body without prospecting your ground. One hundred dollars worth of development would have put him into a chimney of rich ore that would have lasted for years. When the hoisting works are completed on the Nettie, this mine will join the ranks of the ore producers, and will materially augment the already encouraging output of ore from Deer Creek.

MONTANA.

THE PENN YAN.—*Mining Journal*, May 9: Some three years since the Penn Yan Co., after making a phenomenal record in the production of ore, was compelled to shut down its mine, the Penn Yan, located about five miles from Wickes, owing to the workings unexpectedly encountering a large quantity of water. Recently a tunnel has been driven on an adjoining mine, the Blue Bird, which resulted in draining the Penn Yan enabling the company to renew operations, which were so vigorously pushed that on yesterday seven carloads of pay ore were shipped to the smelter, which will be pleasing information to the stockholders, who may look forward to continued shipments. The Blue Bird is also extracting some good ore in the development work, and doubtless will soon begin ore shipments.

HIDDEN TREASURE.—Word came from Castle yesterday that a rich strike was made in the Hidden Treasure.

CUMBERLAND SMELTER.—Work on the Cumberland smelter is rapidly approaching completion and it is hoped that fire can be blown in by the 20th inst.

A NEW DISTRICT.—What promises to prove an important mining district is being opened up on the Lost Fork of the Judith, about 18 miles from Neihart, where O. E. Berg, Doc Potts and others are developing the Sweepstake and Cliff lodes. Assays from these claims return from 150 to 200 ounces silver and from 50 to 60 per cent lead. The ore is a hard carbonate in a formation of limestone and slate. A crosscut tunnel is now in 320 feet and it is anticipated the lead will be struck within 60 feet more.

RIVER DREDGING.—*Billings Times*, May 9: The latest placer mining venture is the big dredge boat now approaching completion on the Jefferson river. It is 90 feet long by 30 feet wide, and fitted with dredging and amalgamating machinery. It will hoist from the river-bed about 1500 cubic yards of sand and gravel daily and save all the gold contained therein. Ex-Gov. Tabor of Colorado is largely responsible for this innovation, and if it is successful several more such boats will be put in. There suit will be that the beds of the Jefferson, Madison and Missouri rivers will be worked out for many miles and if it pays there it will also yield large profits on the Big Horn and Stinking Water.

NEW MEXICO.

PYRAMID.—*Western Liberal*, May 8: The Pyramid company is resetting the amalgamating pans

torn out of the mill some years ago by Superintendent Burns. Mr. Hamilton finds that the concentrators do not take a satisfactory amount of the ore, but that it takes out all the base, leaving the tailings in good shape to be amalgamated. He will thus be able to get the value of the ore without the old expensive method of roasting. In resetting the pans considerable quicksilver was found which had been lost when the pans were in use before, and the mercury has been found all over the mill, showing that considerable had been lost when retorting, and had been precipitated as metal in out of the way places. The amount found was about 70 pounds.

SHIPPING ORE.—*Silver City Enterprise*, May 8: The Teal-Poe mining company of Cook's Peak is shipping on an average five cars of ore per week, which averages 60 per cent in lead and about \$7 in silver. Recently a very extensive body of sand carbonates have been uncovered in the mine, which at the present time is showing more ore than any other property in the camp. At present the indications are that the supply of ore is almost inexhaustible. The owners of the mine adopted an innovation in the formation of their company by taking Lawyer Ashenfelter into the company. The majority of the owners of rich mines employ legal ability to look after their business with the result that in the end the mine falls into the hands of the attorneys.

OREGON.

THE GREENHORN MINES.—*Bedrock Democrat*, May 8: Carpenter Brothers have moved down to their Greenhorn hydraulic mine on Greenhorn Gulch, and intend operating two pipes just as soon as water starts sufficient to handle their giants. The quartz miners have lots of water to contend with on account of melting snow, which makes it had for their work, yet they are still hanging on and think of their costly mansions and brown stone fronts "in the distance." John Platt is now at work on the Greenhorn mountain. He is the discoverer of the Polar Star on the northeast side of Silver hill, which is a part of Greenhorn mountain. The Polar Star quartz claim is very rich in silver. Mr. Platt is driving a tunnel to tap the mine at a greater depth than attained by the original work done the year of discovery. He shows great energy for one of his age, having worked alone all winter, and his tunnel is about 100 feet.

OUTLOOK DEMOCRATIC TIMES. May 8: The mining outlook for Baker county during 1891 is better than for many years past. There appears to be more confidence displayed in the richness and permanency of the mines than ever before, the result of many years' struggling on the part of honest miners, who have toiled ceaselessly to bring their properties to a state of development that leaves no doubt of their value.

UTAH.

THE DEEP CREEK EXCITEMENT.—*Tintic Miner*, May 9: That there is mineral in the Deep Creek country, Dugway and other points lying south and west of Tintic, we have not the least doubt. There are, however, circumstances connected with this same Deep Creek country, that when known, should cause those miners, who are without means other than their ability to perform a day's labor, to pause and reflect before rushing to a country of which they know nothing except the sensational and exaggerated reports which invariably follow the opening up, or discovery of mineral in all new districts. In the country west of us, bordering on the Desert there is virtually no water fit for human use, while provisions are scarce, dear and very difficult to be obtained. Then again there are very few, if any, mines developed so far as to offer employment to any considerable number of men. We do not wish to detract from the value of the mineral field of Deep Creek or vicinity, but to warn the poor, hard working miners of the country against the dangers, hardships and privations, that must inevitably result as a consequence to any mad rush to a new and untrodden country, more especially when that country is little more than a barren desert. Three men walked into Eureka from Deep Creek and Dugway, a few days ago, and gave a most deplorable account of the hardships they endured in that country. They reiterate the statement made above as to the scarcity of water, provisions and accommodations of every kind, while they emphatically state that it was utterly impossible for them to obtain employment of any kind. Their names are Oscar Wilkins, Sidney Worsley and A. H. Graham, and by their general appearance and conversation they impress us as honest, hard working and truthful miners. When capital has so far developed the country under discussion, as to make it safe and profitable for miners to go there, it will be time enough for any such rush as is now being so extensively talked about. There is a vast field here on the great lime and quartz belt of Tintic, where capital can find safe and profitable investment, and where eventually the hardy toilers of the mountains and foothills will find steady, remunerative employment. Water, fuel and all other accommodations necessary to the comfort and happiness of the mining community are found in sufficient abundance to insure the people against want, while the old mines at work and the new ones being opened up, are a sure guarantee of great wealth and prosperity for the district now and in the future.

WASHINGTON.

EVENING STAR.—*Okanogan Outlook*, May 7: The Evening Star is developing into a splendid property. The shaft is now down 40 feet, and in sinking that distance the ledge has increased in width from six to 11 feet, five of which is well mineralized. The mine is located on the opposite side of the creek from the Lone Star and is supposed to be an extension of the Toughnut lead. The John Arthur mine is to be quite extensively developed this summer. Mr. Robison, one of the owners, is now on the ground getting things in shape for business. The mine is located about a mile up the creek from Concomely and is the extension of the Lone Star lead, which it joins on the north. There is already a 40-foot shaft on the mine, and several tons of good ore on the dump. J. M. Pitman is doing some development work on the Linnet, a very promising gold prospect on Palmer Mountain. Mr. Pitman was in town yesterday, and showed us some beautiful specimens of ore, some of which contained lots of free gold.

MECHANICAL PROGRESS

Philosophy of the Bessemer Process.

Steel is really a carbide of iron, and Mr. Bessemer founded his process of making steel by blowing out the excess of carbon from the iron, so that the proper amount, 1.5 per cent, should remain. A brief summary of the Bessemer process may be interesting. If a bar of steel as soft as iron be made red-hot and plunged into cold water, it will become very hard. If it be gently heated, it will become less hard, and is then fitted for surgical instruments. The various shades of steel are carefully watched, the change of color being due to the varying thickness of the oxide, for we know that when light falls upon very thin films of a substance, soap bubbles, for instance, the light reflected from the under and upper surfaces interfere and cause color, which varies with the thickness of the film. These colors in steel correspond to different temperatures, and the "temper" of the steel depends upon the temperature it has reached. The color and uses of various kinds of steel range all the way from faint yellow, for lancets, etc., to dark blue for hand-saws.

The Bessemer process transfers the metal into a vessel in which there are tubes, through which air is forced, which produces a much greater heat than a bellows does. Thus, in the process, the carbon of the iron acts as fuel to maintain the fusion, and at the same time, by the huddling of the carbonic acid, mixes the molten iron thoroughly. During the huddling up of the whole mass of iron, and the extreme elevation of temperature, caused by the union of the carbon of the impure iron with the hydrogen of the air, the oxide of iron is formed, and as fast as it forms, fuses into a sort of glass. This unites with the earthy matter of the "impure" iron, and floats on the upper part as a flux, thus ridding the cast iron of all its impurities, with no other fuel than that contained in the metal and in the air used. When the flame issuing from the converter contracts and changes its color, then the time is known to have arrived when the iron is decarbonized. The amount of carbon necessary is artificially added, ebullition takes place, a flame of carbonic oxide comes out, and the metal is then run into ingots.—*Popular Science*.

Testing the Wire-Wound Gun.

The public test of the Brown segmental-tube wire-wound gun, one of the latest inventions in ordnance, has just been made at Fort Wadsworth, on Staten Island. The special object of this test was publicly to demonstrate the high pressures to which a gun of this type can be subjected safely, far in excess, as the inventor declares, of what guns of other types can endure.

The test was of a cylinder 20 inches long, corresponding exactly to a section of a complete five-inch Brown gun. The segments of which the inner tube of the gun is built up, as a barrel by its staves, are 72 in number; this inner tube is wound with 29 turns of wire at a tension of 50 tons to the square inch. At each end of the tube thus constructed for experimental purposes was sunk a steel cap, and into this was screwed a breech plug. The cylinder was thus entirely closed with the exception of a small vent large enough to admit the electric wire by which the charges of powder were exploded, and the pressures obtained were measured by gauges screwed into the inner face of one of the breech plugs.

The program was to explode successive charges of powder within this closed section of a gun, beginning with a charge of two pounds and increasing till a charge of five pounds was reached, expected to give a pressure of over 50 tons to the square inch. The first two were successfully attempted, but after the third it was found impossible to unscrew the breech plug, showing that the tremendous power of the gun must have fractured the inner casing, and forced or fused the threads of the screw by which the breech plug was screwed on. This was done with a charge of three pounds one ounce, and the pressure that was estimated to result from this was over 60,000 pounds. The inventor, James Hamilton Brown, and Lieutenant G. A. N. Whistler, who had charge of the test, considered that, notwithstanding this mishap, which they say does not affect the principle involved, the value of the gun was fully shown, for such pressures had never before been attained in ordnance.—*New York Tribune*, March 29.

THE TREATMENT OF WIRE ROPES.—There are various ways of treating wire ropes, with a view of their better preservation; but we are not aware that the method recommended by a German engineer are generally known. One method recommended by him is to hold graphite in tallow, and to apply this butter-like mixture either with a brush or to let the rope run through a vessel of trumpet-form filled with the grease. The lubrication has to be repeated about every four weeks. It is said that this treatment is a protection against rust, and prevents abrasion when the rope comes into contact with hard bodies or substances. Graphite grease also prevents the rubbing of the several wires against each other, as it finds its way even into the smallest interstices. Wire ropes cannot be piled like hemp ropes, but must be

laid on the ground in wheel form. To preserve them, the following means may also be adopted. Crude linseed oil is mixed with vegetable tar, and applied to the rope. The mixture forms a protective coating, and reduces wear and tear. In order to preserve wire ropes under water or below the surface, a composition of 35 liters of slaked lime, and from 50 to 60 liters of mineral or vegetable tar is recommended. The mixture must be well hoiled and applied hot. Galvanized wire ropes should never be used as driving ropes. After 24 hours' use, the tin coating is worn off, and the rope soon begins to rust. Great care should be bestowed upon the pulleys. The grooves should be always clean, and the materials with which they are lined—wood, leather, india-rubber, or soft metal—must be of the best quality and durable, in order to lengthen the life of the rope and increase adhesion. Steel ropes are excellent substitutes for iron ropes where lightness or greater strength are considerations.—*Iron*.

A SENSIBLE INNOVATION.—Railroad economy has at last attacked the brass ornamentation of the locomotives, and hereafter all the principal railroad companies in the country will use painted wrought iron and blued steel where formerly burnished brass reflected and multiplied the rays of the sun. The new departure will cause a material saving in the labor of the engineers, the number of extra wipers employed about the shops and the original cost of the locomotives. The late Franklin B. Gowen, while President of the Reading Co., was the first to appreciate the great waste in the profuse use of brass, and he greatly reduced the quantity on all new locomotives built. It is only recently, however, that the use of the metal has been almost entirely abolished, and where formerly a locomotive looked as if dressed out for a holiday, there is to-day nothing but sombre black, giving the machine a very business-like appearance. The Pennsylvania Railroad Co. has also built all its new engines without any conspicuous brass ornaments. Freight engines were the first to begin the economy, which has now extended to locomotives of all classes. One of the officials of the company, in speaking of the change recently, said: "The use of the brass was expensive in many ways. It increased the original cost of the locomotive, took up the time of the engineer and fireman to polish it, besides the work of a large force of wipers in the round-houses. These wipers are now done away with entirely, and the engineer and fireman can clean their engine with a few passes of waste. The new departure has been coming into operation gradually. Old engines were not altered, but they were replaced by better and more business-like machines."—*Philadelphia Record*.

A TEST OF THE SERVE RIBBED BOILER TUBES. A test of the superiority of the Serve ribbed boiler tubes has recently been made at the works of the Samuel L. Moore & Sons Co., Elizabeth, N. J., which has shown a large gain in capacity and economy by the use of the tubes. On the forced draft trials, a pressure of seven-eighths inches of water was used, and the boiler evaporated a third more water in a given time, when fitted with the Serve tubes, than when fitted with the plain tubes. With the plain tubes, the pyrometer showed a temperature of the escaping gases exceeding 1200°. With the Serve tubes, the temperature did not exceed 740°. Further trials were made on April 23d and 24th, to see how strong a draught would be required to bring the temperature of the escaping gases up to the temperature which they had with the plain tubes. A full account of the tests will soon be given to the public.

TESTING STEEL AT LOW TEMPERATURE.—The French Government has caused to be made several tests of gun steel at a low temperature, 75° to 100° below Fahr. Part of the bars were hardened and part unhardened. The breaking load was increased by the cooling three per cent, in the instance of the unhardened bars, and six per cent in that of those hardened. But in a shock, such as a gun would be subjected to, the unhardened bars, cooled, broke on an average with 5.9 blows, against 14.6 blows under ordinary conditions. With the hardened bars the difference was less, 12.57 blows being required for the cold bars, against 14.4 at the normal temperature. The bars, both hardened and unhardened, had their elastic limit raised 11 per cent by the cold, and their elongation was diminished by 12 to 14 per cent. The bars recovered their original properties upon attaining the ordinary temperature.

MATERIAL FOR CAR-WHEELS.—In a recently published account of the works of the Northern railroad of France, it is stated that they have an ingenious plan, in the interests of economy, of making wheels for cars by bending up seven pieces of bar iron in such a shape that the center fits inside a hand or false felloe, which, in turn, is hammered into a groove in the tire. Felloe and bar are riveted together, and the bars bent round to the center of the wheel, and their ends then have a mold placed below them; cast iron is then run in, forming the hub, which is afterward bored out, and the cast-steel axle forced in by 55,000 to 66,000 pounds hydraulic pressure. The life of the center of the wheel is said to be practically interminable under the ordinary conditions, and the cheapness is such that they are now adopted almost entirely.

SCIENTIFIC PROGRESS.

Cratina—A Digestive Ferment From the Fig.

In 1880, in a communication to the French Academy of Sciences, M. Bouehut reported that he had found the juice collected from the common fig tree (*Ficus carica*) to contain a powerful ferment capable of digesting aluminoid substances, thus confirming a belief of the ancients that the juice possesses digestive properties. This ferment is now the subject of a paper by Dr. Mnesi, in which he reports its isolation, and describes its properties. Juice collected from the fruit and branches of the fig was filtered to remove the serous portion from the insoluble, the latter repeatedly washed with water, and the washings added to the filtrate. This liquid, which after repeated filtration, was obtained limpid, was distinctly acid in reaction, and when placed in contact with moist fibrin, digested it completely. It was evaporated to a small volume, again filtered, and treated with absolute alcohol, which threw down a plentiful white precipitate that dried, when exposed to the air, to a dark-yellow amorphous mass. This, when treated with water, swelled up and imparted a milky appearance to the liquid, but a clear filtrate from it, though it gave the reactions of vegetable albumen, had no digestive power. The residue, insoluble in water, dissolved readily upon the addition of a trace of acid or alkali, and the solution, placed in contact with moist fibrin, effected complete and true digestion. To the ferment thus isolated Dr. Mnesi gives the name "cratina," from *krade*, the name given by the Greeks to the part of the fig with which they specially associated the digestive property. It contains nitrogen, and in the dry state it forms a friable, semi-transparent, dark-yellow, amorphous mass, yielding an amber-yellow powder. In water it swells, but does not dissolve, though upon being shaken it imparts to the liquid a milky appearance. When dissolved by the aid of alkali or acid a concentrated solution is dark-yellow, but becomes colorless upon being diluted. Cratina differs from pepsin in maintaining its digestive power in an alkaline liquor, and from papain or papayotin in being insoluble in water, not precipitated from solution by alcohol or lead acetate, and in its activity not being diminished in the presence of hydrochloric acid. In a neutral liquid it is devoid of digestive power and it has no reaction upon starch.—*Pharm. Journal*.

Energy.

Before the Thompson Scientific Club at Lynn, Professor Thompson recently delivered a very interesting address on "Energy." Formerly, he said, matter was considered as the thing that existed, and force the something that acted upon it. Energy is a term used to express something which we do not always understand. It exists everywhere so far as we know. Matter was considered indestructible. If we admit that energy can act on energy, we have no need of the old matter and force. We can see the changes in energy, though we cannot discover the thing itself. We have potential and active energy. Potential is simply stored energy, power to do work. The water in the reservoir is the same as the water a hundred feet lower, but it can do work that the other cannot, because it has energy stored in it. When that water is running down the hill and turning the wheel, it shows its actual energy. The earth revolving is another case of stored-up energy, as is also a wheel in motion. A spring is an example of elastic energy. In a boiler we have kinetic energy transformed from the heat of the fire. These are all mechanical forms of energy. The cannon-ball shot into the air shows energy of motion in its ascent. When it reaches the highest point, it has energy of position. When it strikes the ground and bounds, it shows elastic energy. Besides this, there is energy of temperature, which the hot cannon-ball possesses. This is called molecular energy. If we could take all the heat out of anything, it would become liquid and then frozen. This has been done even to air. There is another or electric energy, another chemical and another radiant. Every form of energy is convertible into any other, sometimes at so great waste as to be impracticable for use. In converting mechanical energy into heat, it is almost perfectly efficient, but in converting heat to mechanical motion, 90 per cent is lost. The energy of heat is disorganized as contrasted with the organized, direct energy of motion. A disorganized army, each soldier going his own way, can do little. The tendency in nature is to degrade energy.

THE NATURAL GAS SUPPLY.—The late utterances of Prof. Orton in regard to the durability of the natural gas supply seem to have stirred up quite a feeling against him on the part of those interested in the continuance of the supply. By late accounts we notice that a resolution has been introduced in the Ohio Legislature calling for an investigation of charges made against the professor as State Geologist in reference to the stand he has taken. The resolution recites that in business circles in New York and elsewhere Prof. Orton has stated the gas supply is not only temporary but rapidly declining, and that such statements

have rendered capitalists timid and kept manufacturers from the field. The resolution further charges Mr. Orton with thus intentionally depreciating the value of natural gas territory to better enable the Standard Oil Company, in whose employ it is charged he is, to obtain control of the business.

Scientific Progress.

Intellect is the great factor in commercial success, whether of individuals or nations. Take the case of the skilled brick-layer and the hod-carrier. The first is using brains on his work; the second is using brute force. When he goes up the ladder with his hod of bricks he has also to carry his own weight—thus wastefully expending force. Some one notices this, and substitutes for the brute force of the human that of the horse; then the horse is displaced by the mechanical force of the steam engine, which can do the work of 15 men or of two horses in the same time. Coal converted into heat is doing all the work. The coal mined each year in the United States represents in actual work more than the sum of the force of the total population of the globe, assuming all to be strong men. Thus the substitution of a natural force for human power vastly increases the productive capacity of the human race.

Guided by intellect, taught by science, the natural forces can do in a few hours what the unaided labor of many men could not do in a lifetime. It was not prophecy, but a flash of genius, that drew from Stephenson the assertion that it is the sun that drives the locomotive engine by being liberated from the coal in which it has been stored for ages. But man can neither create forces nor endow anything with properties; all that he can do is to convert and combine them into utilities. The man that does this with knowledge is spared the dismal failures of ignorance, but he that tries to use powers without understanding them is inevitably punished for his rash presumption. It is this presumption that causes the mortality and disease that follow in the wake of civilization. Natural law, like the civil, never admits ignorance as an excuse.

In this century three scientists have revolutionized commerce—Oersted of Copenhagen, and Faraday and Wheatstone of London. It was Faraday that Huxley said, in effect, that any nation would do well to spend \$500,000 in discovering such a man, and an equal amount in educating and setting him to work. Bessemer, studying away at steel, has revolutionized ship-building. Dr. Joule's studies in the mechanical equivalent of heat produced the compound engine, by which the necessary amount of coal for carrying a given cargo has been reduced more than 40 times, that is, a steamship that in 1850 carried a cargo at an expenditure of 14,500 pounds of coal to a ton, now does the same work by burning about 350 pounds. Joule's studies in heat have made it possible for a cube of coal that will pass through a rig the size of a twenty five cent piece to drive one ton of cargo for two miles in one of the most improved steamships. In 1880 the rate of grain from New York to Liverpool was 9½ pence; in 1886 it was 1 penny a bushel. The reduction was primarily due to the scientist.—*Aluminum Age*.

INDIVIDUALIZING.—Never, since the "world began" says a cotemporary, did the individual man do his own thinking, as he is now doing it. This may bring chaos for a time, for man in a new role does not always act wisely. The labor question is being pushed too rapidly, and disaster for a time may be the result. The manufacturers may be compelled to organize for self-protection as in Australia; then the laborer will suffer. The labor leader never required the wisdom that he does now, not only to gain the greatest benefit at the least cost for those he leads, but even for self-preservation. The day of the cheap politician is rapidly passing, and the voters are looking for men and not cheap clap-trap. They are not turning grid-irones so much as they were, and the party leaders will be as helpless as a herrel in a whirlpool before 1892.

THE WEAR OF RAILS.—A recent German paper makes reference to some careful lists lately carried out to determine the wear of steel rails of different degrees of hardness. The chemical and physical characteristics of the rails tested had been accurately determined, and the test for wear consisted in letting 26,120 trains pass over them during a period of 1833 days. The rails were then thoroughly cleaned and weighed, and the difference between the initial weights accepted as giving the loss from wear and rusting. The tests are said to have shown that the wear thus determined was in about an inverse proportion to the tensile strength of the metal, so that it would appear to be advantageous to insist upon high tensile strengths.

IN THE NEW PROCESS OF MAKING WHITE LEAD the ore as it comes from the mine is volatilized and oxidized by the air, the fumes are condensed by a slightly acid liquor, and the resulting sludge is washed and dried for the market without having been touched by the men. Quickness of manufacture, starting with ore and not with the purified metal, and avoidance of danger to the workmen, are among the advantages of the new system.—*Invention*.

GOOD HEALTH.

Microbes and Disease.

Pasteur was among the first to take up and study the subject of the germ origin of disease. His specialty was hydrophobia. He held that a certain kind of disease germ, when numerously developed in a dog, produced hydrophobia, and that such germ might be communicated by the saliva; but, contrary to the later observed action of microbes, the hydrophobia germs lost their power of communicating their particular disorder (rabies) on becoming dry.

Dr. Henry Gihbons, in a recent lecture at the Cooper Medical College in this city, when speaking of the origin of microbes, remarked that all dead animal and vegetable substances tend to decomposition, creating foul odors and gases and developing microbes. Some of the microbes germs and spores caused by putrefaction would survive boiling in water. Certain of these germs are so small that 28,000,000,000 of them are found in a single drop of water. A drop of water will contain more of these little animals than there are inhabitants on the globe. Enough of them would be germinated in a few days to fill the great oceans, if they all survived. Fortunately they die young.

False ideas prevail regarding antiseptics and disinfectants. Many of the popular liquids merely destroy bad smells by worse odors. Boiling water and heated moisture are among the best and cheapest disinfectants. Heat will destroy the germs of scarlet fever and small-pox. Spores when dried are exceedingly hard to kill. Some will survive boiling water. Enforced cleanliness and soap and water are a preventive, but beyond their powerful disinfectants are also necessary.

Modern research seems to show that nearly or quite every disease has its peculiar microbe, the germs of which may lay dormant in the system until some peculiar condition is present under which they may be developed. The same peculiar condition may also render the system susceptible to their entrance from without.

The Relation of Microbes to Nose and Throat Diseases.

At a recent meeting of a British Medical Association, Dr. John MacIntyre, of Glasgow, Scotland, gave an interesting lecture on the relation of bacteriology, to diseases of the nose and throat. In the course of his lecture as reported in the London *Lancet* the doctor discussed the general facts concerning bacteriology, such as classification, vital phenomena, etc., and stated the arguments for and against the vitalistic theory of disease. He demonstrated a large number of specimens of well known forms of micro-organisms under the microscope, as well as numerous micro-photographs on the screen, and made special reference to those of interest in throat and nose work. He showed several found in the mouth and nose of healthy people, which are apparently harmless, and others found in diseases where there is decomposing material such as in cancer. He referred to the specific forms found in diseases of the lower part of the respiratory tract, as tubercle, lupus, diphtheria, pneumonia, and suppurative diseases.

Lastly, he discussed the question how protection was to be got from the diseases associated with micro-organisms, noting the result of inoculation. He explained some interesting experiments recently made in Glasgow with reference to the hypodermic injection of chemically pure carbolic acid, which he thought had far to demonstrate the possibility of rendering the effects of certain micro-organisms inoperative within the body. In considering the possibility of rendering the tissues unsuitable for the growth of organisms after their entrance into the system, he cautioned his audience not to be carried away too hastily by Koch's or Liebreich's methods of treatment for tuberculous.

As a word of caution to accompany the above we give the following paragraph from the pen of a writer in a New York journal who, in commenting upon the report of the *Lancet*, says: "The remedy proposed for ordinary throat and nose diseases may be worthy the consideration of physicians who have cases of la grippe under their charge. It is a fact that the latter disease is very prevalent in a great many of our populous places, and that it seriously affects the nose, throat and respiratory organs, and it is not improbable that the cause may be produced by some form of bacteria which the remedy proposed may relieve. But persons should beware of the use of carbolic acid in the manner suggested, except under the direction of a skillful physician."

CURIOUS ACCIDENTS.—Mrs. Eliza Foster, 59 years, of Philadelphia, recently fractured a rib while trying on a pair of boots at a shoe store. As Mrs. Foster was pulling one of the boots on her foot a crack was heard, and she complained of great pain. She was taken to the hospital. Here, says the Philadelphia *Press*, is the 45th case of the kind known to the medical profession. Another remarkable case is reported of a needle which had found its way into the body of a Springfield, Mo., woman and which after a devils-experience and travel of 35 years, came out through her side the other day. The needle had lost its temper and was as pliable as a piece of wire. Still another, a wonderful case, of a Pennsylvania woman, 79

years old, has recently been reported. The woman who had been bent double with rheumatism for many years, and was two-thirds of the time confined to her bed, is said to have been completely cured by the fright caused by discovering a snake in the chimney. She is now entirely free from pain and is as erect and agile as a woman of 20.

ELECTRICITY.

Electrical Progress.

Practical progress in electrical matters has quite outrun the literature of the art. So eager have been inventors and machinists to advance in this art that they have kept quite ahead of the scientists in their experimental studies. As a consequence, some mistakes have been made. This is also one of the chief reasons why so many accidents have resulted from the introduction of this new agent into the mechanical and other economies of the day. The science of electricity is not studied as thoroughly as it should be. Our institutions of learning, from the common school up, are in the background in this respect. The recent increase of periodical publications are largely helping to bring up this work.

Prof. Silvanus P. Thompson of London, England, has recently given to the world a series of four lectures in book form, which have added much to the needed literature in this direction. In his efforts to supply this great need, the professor has conducted a most thorough search through all the old and new English, French and German publications for records of reliable experiments and data about electro-magnets, and after collecting them and drawing his conclusions, added to them the result of numerous and original experiments of his own and presented them before the Society of Arts, London, in the form of lectures, which constituted one of the sets of Cantor lectures of the session, 1889-90.

With indefatigable labor, Prof. Thompson succeeded, by means of tables and simple formulae, in reducing the calculations concerning electro-magnets to such a practical shape, that the calculation of a magnet, to develop a definite number of lines of force, or to exert a pull of a definite number of pounds, is now a comparatively simple matter to a person possessing fair mathematical ability.

The first lecture contains a historical sketch of electro magnets, in which many of the famous magnets of the early days are described as well as many of the experiments made with them. The typical forms of magnets are briefly described next, and then comes a very clear and interesting discussion of the magnetic properties of iron and the methods of measuring permeability. A shop method of roughly estimating the permeability of iron by means of the "permeameter" devised by Prof. Thompson, is given and seems well suited to that purpose, as many of the objections to other methods are avoided. The lecture closes with a short and clear presentation of the phenomenon called "Hysteresis," and an interesting and instructive list of "fallacies and facts about electro-magnets," many of which will astonish and surprise any one on first reading.

The second lecture is devoted chiefly to the general principles of design and construction. The principle of the magnetic circuit and the deduction of the formulae is discussed in a very lucid way.

The third lecture takes up the question of the winding of magnets. Many common-sense directions and suggestions are given and also a wire gauge and amperage table which will prove of great value to the designer of magnets.

The fourth in the series is devoted to electro-magnetic mechanism, and gives principles and magnetic directions for calculating magnets whose armatures are to have definite motions.

ELECTRICAL CRANES AND HOISTS.—A writer in the London *Iron Monger*, says that some things are done better in the United States than in England, but that in some other things the converse holds good. In some of the applications of electricity that journal says the English are decidedly behind our American cousins, and particularly in respect of its use for cranes and hoists. Incidentally, it may be remarked that Switzerland, France and Germany are also moving faster in these respects than we are in Great Britain. The subject was dealt with briefly in a paper by Mr. W. D. Sandwell, read before the South Staffordshire Institute of Iron and Steel Works Managers on April 11. The paper is short but suggestive, and the subject generally merits much more British attention than it has yet received.

Electrical cranes and hoists are capable of being used with success and economy in situations where other forms of power could scarcely be made use of at all. For building purposes such cranes are especially adapted, and in permanent structures they are very advantageous. In the United States, pig iron, machinery, and so forth are efficiently handled in this manner. Mr. Sandwell is of the opinion that our large docks could be fitted with electric gear much cheaper and far more efficient than the hydraulic power now used. In a large installation of this kind a total efficiency of 60 per cent. could be maintained, as against 40 per cent. from hydraulic power and 30 per cent. from compressed air.

USEFUL INFORMATION.

THE PHILOSOPHY OF ARTIFICIAL ICE MANUFACTURE.—The scientific fact on which the making of artificial ice depends is that when a liquid evaporates it uses up a great deal of heat, which it draws from anything that happens to be around it. If a can of water is at hand, its temperature is reduced, and if the action goes far enough the water will be frozen. This cooling action can be felt by pouring a little ether or alcohol upon the hand. The liquid evaporates rapidly, and the loss of the heat which it takes up cools the hand very perceptibly. If a bottle containing water is kept wet on the outside with the ether, the evaporation will chill the water and eventually freeze it. This is eventually the process by which the *cafés frappés* of French restaurants are produced. The decanters filled with fresh water are set in shallow tanks containing brine, which remains liquid below the temperature at which fresh water freezes. In contact with these tanks are receivers, which can be kept charged with newly formed ether vapor. The chilling vapor cools the brine, and this in turn takes heat from the water in the decanters, which soon freezes.—*Pop. Sci. Monthly.*

SHADING GREEN HOUSES.—There is some difficulty in choosing a shading for green-houses, as some materials wash off too quickly and others not readily enough, as in the case of the common lime-wash. A correspondent in the *Gardener's Monthly* says he has tried many materials, but all have proved unsatisfactory. He found the following, however, very useful for many other purposes besides shading: Take one pound common whiting, one ounce of the best glue, and a quarter of an ounce of bichromate of potash, called also red alum. Soak the glue the day before using, melting in a common glue-pot, and then dissolve the bichromate in warm water. Mix the materials together and thin them down to the consistency required. These, after being exposed to the light, are almost as adherent as oil paint. Of course, by reducing the proportion of bichromate, the material can be made less retentive, but a coat of this wash on the greenhouse will last the whole summer, and even he troublesome to wash off, not to such a degree, however, as lime-wash. It should be constantly stirred up while being used.

ALLIGATOR AND CROCODILE.—It is said that only five crocodiles have ever been captured in Florida, although alligators are numerous. One difference between the two is that the crocodile works his upper jaw, while the alligator snaps a man in two with his lower jaw.—*Ex.* The alligator and crocodile are both of the same family, which includes three genera, the *Gavialis*, *Crocodilus* and *Alligator*. The type of the first is the "gavial" of India, the second the "crocodile" of Egypt and the third the "alligator" of America. The last named is peculiar to this continent. It was first discovered by the early Spanish voyagers, and thought to be identical with the crocodile of the old world; but scientists have since found distinctions to exist which indicate generic differences. It may become an interesting question among scientists, if the crocodile of Egypt has been found in Florida—how did it get there? Is it a variation in nature, or has that particular specimen of the San Juan family been recently transported from its native waters to those of Florida?

ASBESTOS FOR THEATER CURTAINS.—The building laws of most of our large cities now compel the use in all new theaters of fireproof drop curtains. The great weight of iron curtains has led the managers of many of the best theaters to adopt asbestos as the best fireproof material for the purpose. An asbestos curtain is light in weight and can be lowered or raised in a few seconds of time with little effort. It does not require a heavy rigging to hold in place. It is flexible and will fold or roll into small compass if necessary. In appearance it resembles cotton duck, and it can be painted or decorated. In use it completely protects the audience from any fire which might originate on the stage.

THE PROCTOR TOWER.—The proposed Proctor steel tower at the World's Columbian Exposition, says the *Engineering News*, is to be 1155 feet in height, and will resemble the Eiffel tower in its general appearance. It will be hexagonal in plan, instead of square, however, and will have a larger base and start at a smaller angle with the vertical than the Eiffel tower. The estimated cost of the tower is \$3,000,000. There is but little probability that it will materialize.

THE LAQUER used in chandelier work is made of shellac dissolved with 95 per cent of alcohol, very thin, slightly colored with dragon's blood. It should stand a few days for the insoluble portion of the gum to settle before being used. The clear laquer should then be poured off and filtered.

The first horse-car made its appearance in New York City in 1832. It was made by John Stephenson in the preceding year, with seats running lengthwise and had also seats on top.

TO CUT GLASS VESSELS neatly, fill the vessel the exact height you wish it to be cut with oil of any kind; then dip, very carefully, a red-hot

iron in the oil. This will heat it all along the surface, and when the upper portion cracks all round, you can lift it clear off by the surface of the oil.

MONKEYS IN FLORIDA.—A colony of 200 or 300 monkeys is reported to exist in the everglades of Florida. They are supposed to owe their origin to the wreck of a vessel upon the coast having on board monkeys, which escaped into the forest.

SHOP NOTES.

BELTS.—When first put on, belts are always made tighter than they need to be for the work required, in order to allow for the stretching which is sure to follow. They are then run until they become too loose for efficient service and the process of overstraining and stretching is repeated. When vertical, this stretching of the belt acts directly to loosen it, and the necessity for tightening occurs more frequently than it does on horizontal belts, where the weight between pulleys maintains more or less tension in the slack side. For this reason a long horizontal belt can hardly be made to slip, without working it to destruction, while the driving power of a vertical belt depends directly upon its initial tension, and this must be carefully looked after to obtain the best results. The position in which a belt may run does not affect the size required for any given duty, but it does affect very seriously the amount of care and attention required to keep it in efficient service.

SHARPENING EDGE TOOLS.—A German scientific journal says: "It has long been known that the simplest method of sharpening a razor is to put it for half an hour in water to which has been added one-twentieth of its weight of muriatic or sulphuric acid, then lightly wipe it off, and after a few hours set it on a hone. The acid here supplies the place of a whetstone by corroding the whole surface evenly, so that nothing further than a smooth polish is necessary. The process never injures good blades, while badly hardened ones are generally improved by it, although the cause of improvement remains unexplained. At length this process has been applied to many other cutting implements. The workmen, at the beginning of his noon spell, or when he leaves it in the evening, moistens the blades of his tools with water acidulated as above, the cost of which is almost nothing. This saves the consumption of time and labor in whetting."

GEAR TEETH.—It has been said that gear teeth should be designed strong enough to carry the whole load on one side of the tooth, but there are places where the teeth are obliged to take care of the load at a greater disadvantage than this. In out gears the teeth fit in together very closely and a short driving shaft has not far to get out of line before the teeth will bind cornerways and come snapping off. It may do for pulleys and belts to operate in this fashion, as that appears to be one of the great points in their favor, but with closely fitted gearing the trouble lies in the alignment of the shaft and gear stands when the teeth are breaking out.

SPIRAL SPRINGS.—The proper way to use a spiral spring is under a state of compression, provided that the first coil of the spring can be taken care of properly, but when this is done there comes in another element that disturbs the proper working of the spring. The coil does not keep in perfect alignment while being compressed to its full extent, but sets off corner ways a trifle, and gives a hind such as no ball and socket joint has been able to relieve. The proper way out of this difficulty is to adjust the spring to set in line while under about a two-thirds load, and let it take care of itself in all other positions.

LATHE TOOLS are made right and left-handed, and like everything else in this line seem to come just wrong, or at least one hand tool will be getting into the place of the other. Lathe tools only appear right in this respect when they are viewed from the back side of the lathe; then a right-hand side tool will be seen standing over to the right and cutting toward the face plate, and the left-hand the other way, the reason no doubt depending on the tools for cutting right and left-hand screw threads in the lathe.

WOOD WORKERS are very fond of having everything set enough to touch up easily with a file. It is a great saving in time to stop a planer, or molding machine, and put on an edge by hand power rather than disturb the set of the machine. The wood turner plays the same trick when he holds the edge of his tools hard against the work to turn them line, that he may bring up an edge with the file, as there is nothing else that will get around the spurs of a parting tool.

THERE is a natural law relating to belting which is not generally known, but which is nevertheless of value in practice. The hug or adhesion of a belt is as the square of the number of degrees which it covers on the pulley. For example, a belt that covers two-thirds of the circumference of a pulley requires four times the power to make it slip as it does when it covers only one-third of the same pulley.

TABLE OF CONTENTS.

EDITORIALS.—The Oldest Quartz Districts; A Bryan Mill Plant; An Electric Mill Tramway, 305. Passing Events; The New Mining District in Utah; Economy in Burning Fuel; Buried Treasures in Gravel Mines; California Mines, 312. Lansill's Mining Balance, 313.

ILLUSTRATIONS.—Electric Tram-Car for Mills; Bryan Mill Plant for Working Gold Ores, 305. Balance for Equalizing Strains on Winding Gears in Mining Shafts, 313.

MISCELLANEOUS.—Observations in Colorado and Utah; Academy of Sciences; Electric Transmission of Power; Sanding Samples; Dealing in Silver Bullion; Cutting Timber on Public Lands; Breyfogle; Steps to Circulate Silver, 306. Gas Treatment for Toxics; Minerals in the Big Horn Mountains; A Virgin Field for Prospectors; Gum in Ramie Fiber; Immersed in Molten Metal, 307.

MECHANICAL PROGRESS.—Philosophy of the Bessemer Process; Testing the Wire-Wound Gun; The Treatment of Wire Ropes; A Sensible Innovation; A Test of the Serve Rihed Boiler Tubes; Testlog Steel at Low Temperature; Material for Car Wheels, 310.

SCIENTIFIC PROGRESS.—Grains—A Digestive Ferment from the Fig; Energy; The Natural Gas Supply; Scientific Progress; Individualizing; The Wear of Ralls; Miscellaneous, 310.

GOOD HEALTH.—Microbes and Disease; Curious Accidents, 311.

ELECTRICITY.—Electrical Progress; Electrical Cranes and Hoists, 311.

USEFUL INFORMATION.—The Philosophy of Artificial Ice Manufacture; Shading Greenhouses; Alligator and Crocodile; Asbestos for Theater Curtains; The Proctor Tower; Miscellaneous, 311.

SHOP NOTES.—Belts; Sharpening Edge Tools; Gear Teeth; Spiral Springs; Miscellaneous, 311.

MINING SUMMARY.—From the Various Counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 308-309.

MINING STOCK MARKET.—Sales in the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, etc., 316.

MARKET REPORTS.—Eastern and Local Metal Markets; Coal and Coke, etc., 316.

Passing Events.

River mining by dredges, which has been successful in Australia and unsuccessful in this country, is about to be tried on the gravel bars of the Jefferson and Madison rivers in Montana. Very large and powerful dredges are being built by a company principally composed of Denver capitalists. New machinery is also being put on the dredge on the Carson river, Nev., the machinery formerly in use being faulty. The bed of the Carson will soon be prospected by this dredge.

Mining work is to be renewed this summer at Big Bend, Butte Co., and the river is to be turned into the great tunnel in July. They expect three months' work in the river bed. This enterprise was abandoned two years ago, and the electric-power plant removed. Steam power is to be used this time for the derricks and pumps, and two places in the river bed are to be thoroughly tested.

There are a good many prospectors in Alaska looking for placers and quartz. That Territory offers a wide field, and some very rich gravel has been found. The climatic conditions are not such as to permit work along the Yukon river in winter, so that the men have to be satisfied with a short season. Well-equipped quartz mines, however, can be worked the year through.

CLEMENT F. WOOD, a Comstock pioneer, and who was at one time Superintendent of the Del Monte mine, died in this city this week.

COMSTOCK mines produced 4095 tons of ore last week yielding \$117,432.

The New Mining District in Utah.

A great deal has been said and written lately of the new discoveries being made in the mining region of Deep Creek, Utah. Lying in Tooele county, west by south of Salt Lake, some 130 miles from the latter place, and reaching well into White Pine Co., Eastern Nevada, it bids fair to become of very great importance. From such information as we have at hand, we are led to believe in the practical existence of a district fully 20x30 miles in extent, with high and low grade smelting ores in abundance, although in a region almost devoid of wood and water.

We have been watching the progress and development of Deep Creek with considerable interest for some weeks, but have refrained from making any prominent mention, any more than can be found in our general "Mining Summary," for fear of the very depressing and disastrous effects produced by mining booms that fail.

From the Salt Lake Tribune, the Salt Lake Stock Exchange, whose officers have lately communicated with us on the subject, we are forced to believe in the existence of a new mining district, at Deep Creek, of great extent and richness.

The formation carrying the ore deposits in Eastern Nevada is mostly granitic, while that of the main portion lying in Tooele county, Utah, lies in porphyry with a limestone contact; the ore carrying sulphides, chlorides, and horn silver quite freely, with a small showing of gold, while others range from 5 to 40 per cent in lead, with from 10 up to many hundreds of ounces in silver. It seems only necessary to mention one claim, among the many, that are already becoming celebrated for their richness in this district, to get some idea of the extent and value of the new discoveries.

The Buokhorn located in about the center of the district, as at present developed, has a width of from 12 to 14 feet, and is traceable for nearly 1000 feet, all carrying pay ore. The dip is almost perpendicular, with footwall of porphyry, and hanging-wall of limestone. The assays show for first-class ore 602 ounces in silver with 9 ounces in gold, and for second-class 136 ounces silver and 2 ounces of gold, all averaging about 10 per cent in lead.

Some of the ores from this mine have yielded as high as 800 to 1800 ounces in silver with 10 to 12 ounces in gold; a showing that is apt to make mining men feverish, and lead many into unnecessary expense and privation.

The country lying between Salt Lake and the new district, so far, has not been a very pleasant one to travel over, there being a scarcity of wood and water, with several barren desert wastes to cross before reaching the mines.

Stage lines from Salt Lake are already projected, with one now in operation, and even a railway is seriously talked of. With transportation facilities completed, and the ready adaptation of the American miner to new fields of enterprise, the district promises to soon be prominent in the mining world. Pipe lines are already projected to carry water from springs and streams adjacent to the mines, while artesian wells are quite possible and practicable in the future.

There are already several sub-districts at Deep Creek, with nearly 300 claims recorded. Salt Lake City is the initial point at present, from which nearly all prospecting parties outfit and make their start for the new mines. That City, Utah and Eastern Nevada, are to be congratulated on the new find, which, if our information be true, will revolutionize all that part of our country and shower benefits over the whole land.

STANFORD UNIVERSITY.—It is now tolerably certain that the first school year of the Leland Stanford Jr. University will begin October 1st. It will be divided into two half-year terms, ending respectively in February and on Commencement Day, June 15th, with the usual Christmas and Easter holidays. While the tuition in the main will be free, board in Madrono Hall will be \$3 a week and rooms will be \$1.50 a week, including attendance. The faculty thinks the actual living expenses of the students may be limited to \$200 a year. Students who apply for admission to the freshman class must be at least sixteen years of age. Men of mature years who desire to make special studies will be required to pass an examination except in English.

Economy in Burning Fuel.

It is stated that nature has furnished us with fuel in three forms, solid, liquid and gaseous; solid the most common; liquid containing the greatest energy; gaseous the most convenient for use; and that the average yearly production of petroleum for the last ten years in the United States was, say 24,165,920 barrels, equal to 3,310,400 tons, against 150,000,000 tons of coal mined in 1889. Now as the energy of oil is practically 50 per cent more than that of coal, if all the oil taken from the ground last year had been used for fuel, it would have displaced on this basis, 4,965,600 tons coal only; but assuming that oil could deliver in practice double the energy of coal, it could then displace only 6,620,800 tons, and we would still require 143,379,200 tons for heat.

So that oil cannot play an important part in supplying our heat requirements. The natural gas used in 1889, it is estimated, contained energy equivalent to from 12,000,000 to 15,000,000 tons of coal, or more than twice the energy of the oil production of the country for the same time.

Now while it is generally admitted by scientists that California holds within her borders vast deposits of petroleum; we are still large consumers of coal; and any process of fuel burning that will lessen that consumption 10 to 30 per cent, would confer an almost incalculable benefit upon our State.

The ordinance passed by the municipality of the city of Chicago, prohibiting any but "smoke burning" contrivances under boilers for making steam, has been attended with beneficial results; clearing up the smoke and soot laden atmosphere of that city, and accomplished with an absolute saving in the consumption of fuel; all being claimed to result from the experiments and practice of the Chicago Heat Storage Company.

This company is now making plans and conducting experiments with a view to the general adoption of their methods in the city of San Francisco and other parts of the Pacific Coast. Their process and patents, as far as understood, comprise the turning the fuel into gaseous matter before it is ignited or consumed under the boiler; this being accomplished by the use of a "producer," or retort, where the wood or coal is ignited, turned into gaseous matter, assisted by the use of a jet of steam flowing into the bottom of the producer.

The oxides, carbons and other combustible material, now in a rarefied form, are forced under the boiler by the steam and the natural draft from the smoke-stack, when ignition takes place. In addition, a system of brick checker work is used under the boiler to confine, partially retain, and to force the flame and heat up against the boilers. It is claimed that in addition to the cleanliness and certainty of combustion, that from 20 to 40 per cent can be saved over and above the fuel consumption, as practical in California at present.

The process looks plausible and will possibly effect all that is claimed for it, yet a practical demonstration will be necessary to prove its value.

Fuel-saving "processes" do not always save fuel. A few years since some tests were made here of the fuel-burning process of a certain Fuel Economizing Co., which had obtained a very favorable contract with the Southern Pacific R. R. Co. for the sale of their method, provided it was a success. After some preliminary trials at the works of the Market Street Cable Railway, the steamer Piedmont, plying between San Francisco and Oakland, was selected on which to make the test, the design being to give the Fuel Co. a six-day's trial and the same to the Railway Company.

The process of the Fuel Co. consisted in the mixing of a decoction of holling hot water with certain proportions of ammonia, salt and rosin, and which was then sprinkled over the coal, using about 60 pounds per ton.

The Topeka people were given the coalyards and sheds at Oakland, to prepare and handle the coal, without restraint or hindrance. The boat at that time was consuming 84 tons of coal every 48 hours, the fuel being delivered in tank-cars, containing 1000 pounds of coal each. Apparently the fuel company was making quite a success, as they gained some three or four tons of coal, above the boat's usual consumption, in the first 48 hours.

This, however, was easily accounted for, as

it was found that the tanks were being rammed and packed. The coal tanks, that were usually received and averaged by the boat engineers at 1000 pounds each, were found to weigh 1150 to 1250 pounds coal each. This part of the process was soon stopped, and the tanks averaged and weighed thereafter, throughout both trials. The tests were made, as nearly as possible, identical as regards time, pressure of steam, revolutions, consumption of water, etc.; with the result that the boat came out ahead of the process, in her six days' trial, about 4000 pounds.

As the master mechanic of the railroad company stated, it took the extra fuel consumed by the Fuel Co., over and above that of the boat, to burn off the water they had put on the coal?

The trials of the Chicago company (which is quite a different concern) will be noted with some interest here, as our coal fields are not very extensive on the Pacific, fuel being high priced, and any tangible saving in its consumption would meet with ready appreciation. A trial has already been made of a part of the Chicago process, at the works of the California Powder Co., but without very appreciable results. The Powder Co., is consuming Santa Paula petroleum, and getting the very high evaporation of 13.85 lbs water to 1 lb of petroleum, a result probably not surpassed in the United States, and which was but faintly added to in the experiment of placing brick checker work or combustion chambers under their boilers.

California Mines.

In another column is a communication from Almarin B. Paul, the well-known California miner and millman, giving the result of some recent observations in Colorado and Utah. Mr. Paul, like others who go from here to Denver, is impressed with the life and enterprise of that place, and the chances that miners have to obtain capital for mining enterprises. Time was when San Francisco was the center for such enterprises; but in these days, men go elsewhere to obtain capital for mining development. It is unfortunate that this is so, since the best properties are fast going into the hands of capitalists from other places. When men come here now to enlist the attention of capital, they have great difficulty in even obtaining a hearing, and the encouragement is so small that a second visit is seldom made.

This being the case, and the dependence of the mining community for capital being in relation to "outsiders," Mr. Paul's suggestions in relation to the coming World's Fair are strongly to the point. We must advertise our mines outside our own borders, and there will never be a better opportunity than the fair will offer.

Thus far the main subject in connection with the World's Fair, as far as California is concerned, has been the appointment of a horticultural man, and the settlement of this question seems to have put everything else in the background. The matter of display of fruits and wines is being worked up, but nothing is said about the mining interests. No representative of that industry has been chosen on the Commission from this State; nobody has been selected to look after a special mining display.

As Mr. Paul remarks, California can make a better mining display than any State in the Union if she chooses, since the variety of her mineral products is greater; but there is no time to lose. If anything worth the while to do is to be done, a commencement should be made at once and the mining community should demand that a decent share of the appropriation should be set aside for the mining industry. Capital is wanted here in mining as well as to buy up the lands which are for sale for agricultural purposes.

LEAD ORES.—The Collector of Customs at Eagle Pass, Texas, has been instructed by the Treasury Department to treat as lead ores all alleged silver ores composed of a mixture of ores or concentrates from different mines, pending a review by the District Court of Texas of the decision of the Board of General Appraisers sustaining the protest of an importer against the Collector's assessment of duty on certain alleged silver ore.

THERE are 1600 people living in Bisbee, Arizona, and there are 900 men at work in the mines.

BALANCE FOR EQUALIZING STRAINS ON WINDING GEARS IN MINING SHAFTS.

Lansell's Mining Balance.

The "Bendigo balance," the invention of Mr. George Lansell of Landhurst, has been introduced into many of the mines of Victoria, Australia. The apparatus is for the purpose of equalizing the strain on winding gears such as are used in mining shafts and warehouse lifts. The invention consists mainly in coupling the auxiliary winding drum or spider to the shaft of the main winding gears, and in attaching to this auxiliary drum or spider a rope or chain of increasing weight to act as a counterpoise to the cage and hoisting rope. This rope or chain hangs down either the pump shaft or down a blind shaft or bore-hole adjacent to the winding gears.

If motion continues, the parts assume positions as in Fig. 3, cage *c* being lowered and cage *c'* being raised, the counter-chain being

drawn up from its receptacle *H*, acting then as a counterbalance to the hoisting rope *c'* of the cage *c*.

The application of this invention to a warehouse lift is shown by reference to Fig. 5, wherein the rope *f'* of the counterbalance chain *f* is simply wound in the reverse direction on a drum or main shaft of winding gear in a manner so that its whole weight will act as a counterbalance to rope and cage.

The drawings in detail given herewith almost explain themselves, and to which we refer the reader in a general way, as a lengthy, detailed description would but add complications to a very simple and useful invention.

In the accompanying drawings, Figs. 1, 2, and 3 are sectional diagrams illustrating the invention; *a* and *a'* representing the shafts of a mine, and *b*, the pump shaft, *c* and *c'* being the cages, *c''* and *c'''*, the hoisting ropes, wind-

ing over the guide. Pulleys *c''* and *c'''* leading to the main hoisting drums *d* and *d'*, shown in Fig. 4. In pump shaft *b* he denotes the receptacle for the counterbalance chain *f*, its upper end being attached to a small rope, *f'*, which leads it to the auxiliary counterbalance pulley *e*, as shown in Fig. 4; *d''* is the drum shaft, so arranged that it can be coupled to winding gear by a clutch as *e'*; *g* shown in Fig. 6 is a pivoted clip securing the leading counterbalance rope to auxiliary drum *e*, and so arranged as to admit the rope or chain being wound in reverse directions.

Fig. 4 is a plan of the winding gear, showing the improvements applied thereto. We omit Fig. 5 of the original drawing, as it only illustrates the application to a warehouse lift. Fig. 6 represents a front elevation of auxiliary drum or spider. Fig. 7 is a vertical section on line *yy*, Fig. 6. Fig. 8 is a vertical section

on line *yy*, Fig. 7. Fig. 9 is a vertical section of receptacle for counterpoise chain, and Fig. 10 is a similar view to Fig. 9, but showing the chain in the receptacle.

Assuming the parts to be in position shown in Fig. 1, motion is transmitted to the winding gear in the direction by the arrow, thus raising the cage *c'*, and at the same time lowering the cage *c*, and counterbalance chain *f*, until the various parts assume the position as in Fig. 2.

A BIG JUDGMENT.—The suit of Charles Peyser against the Oro Flat Consolidated Mining Co. for \$34,246.30 principal and \$175.76 interest on a promissory note executed January 2, 1890, has been decided by Judge Wallace in favor of the plaintiff.

F. L. RANSOM has been appointed student assistant in the department of mineralogy and geology at the University of California.

EDWARDS' WORKS ON THE STEAM ENGINE.

The American Steam Engineer. Theoretical and Practical; with Examples of the Latest and Most Approved American Practice in the Design and Construction of Steam Engines and Boilers of Every Description. For the use of Engineers, Machinists, Boiler Makers, and Students. By Emory Edwards, M. E. Illustrated by 77 engravings. 12mo, 419 pages.....\$2.50

Modern American Marine Engines, Boilers, and Screw Propellers. Their Design and Construction. Showing the Present Practice of the most Eminent Engineers and Marine Engine Builders in the United States. By Emory Edwards. Illustrated by 30 large and elaborate plates. 4to.....\$5.00

The Practical Steam Engineer's Guide in the Design, Construction and Management of American Stationary, Portable, and Steam Fire Engines, Steam Pumps, Boilers, Injectors, Governors, Indicators, Pistons and Rings, Safety Valves and Steam Gauges. For the use of Engineers, Firemen and Steam Users. Illustrated by 119 engravings. 420 pages, 12mo.....\$2.50

A Catechism of the Marine Steam Engine. For the use of Engineers, Firemen, and Mechanics. A Practical Work for Practical Men. Illustrated by 63 engravings, including examples of the most modern engines. Fifth edition, thoroughly revised, with much new matter. 12mo, 414 pages.....\$2.00

Modern American Locomotive Engines. Their Design, Construction and Management. Illustrated by 78 engravings. 12mo, 383 pages.....\$2.00

The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

Illustrated circulars, showing full tables of contents of all of the above valuable books, will be sent free to any one in any part of the world who will send his address.

Our new revised Descriptive Catalogue of Practical and Scientific Books, 87 pages, 8vo, and our Catalogue of Books on Steam and the Steam Engine, Mechanics, Machinery and Dynamical Engineering, and other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.

Civil and Mining Engineer,
MINING EXPERT AND GEOLOGIST.

Address "Business Box A," office of this paper, San Francisco.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and absolutely water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated, Price, \$2 each, or the entire instrument finished in gold plate, \$5.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By Guido Kustel, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 166 pages, embracing illustrations of furnaces, supplementors and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, cloth, postage free. Sold by Dewey & Co., Publishers, 220 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by Dewey & Co., S. F.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy. Price, \$3.00 post-paid. Sold by Dewey & Co., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E. The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from ornate as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

THOMAS PRICE & SON,

GOLD MINES

—AND—

STOCK IN MINES FOR SALE.

Dividend-paying Mines from \$150,000 up. Undeveloped Mines from \$10,000 up. Undeveloped Mines on Bond. Stock in Dividend-paying Mines from \$1 up. Stock in Undeveloped Mines now being opened from 25 cents up.

All situated in the ORASS VALLEY MINING DISTRICT, the Oldest Quartz Mining District on the Pacific Coast, and the Richest and most Permanent in the World. The mines of this district are practically inexhaustible, as nearly half a century of constant working is proof. Orass Valley has the deepest regular dividend-paying gold mines in the world, and the end is not yet, for these same mines are as rich to-day as at any time during their history.

Gold mining, especially in Orass Valley, when under honest and scientific management, is one of the safest and most profitable of all American industries. It is a business that will return annually a profit of from 100 to 300 per cent on the investment. Mining is a science acquired only by years of study, combined with practical experience. Therefore, failure is the rule whenever the management is ignorant and unscientific.

The undersigned is a practical scientific and successful miner, has made mining a life study and vocation, is honest and trustworthy, and will not, under any circumstances, recommend or deal in any but valuable paying property and properties that will develop dividend-paying.

No Wildcat Mines; no Sharp Practice; no reasonable chance for loss; Honesty and Square Dealing Guaranteed. Correspondence solicited. Full particulars by applying to

S. B. FOWLER, Supt. Hartley Mine, Grass Valley, Nevada Co., California.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, May 14, 1891.

Cool moist weather the past week is accepted as favorable to growing crops. Among the better informed it is believed that the output of wheat will be all of 1,800,000 tons in this State; this means with good prices an unusually prosperous fiscal year in this State. The local money is fairly easy. General trade for the season is good.

QUICKSILVER—Receipts the past week aggregate 134 flasks. The market is fairly steady at current quotations.

MEXICAN DOLLARS—The market is quiet at 78 to 78½ cts. Holders do not appear disposed to press sales.

SILVER—Purchases by the Department are reported as follows in this month:

Date.	Offered ounces.	Purchased ounces.	Price paid per ounce.
May 1.....	789,000	350,000	\$.9700 to \$.9840
May 4.....	346,000	\$.9850 to \$.9870
May 11.....	593,000	\$.98125 to \$.9825
May 18.....	144,000	\$.97950 to \$.9890

The market continues unstable both at home and abroad. The feverish condition of European money centers is undoubtedly against silver, but with the return of confidence, its market value will be largely advanced by reason of its gradual absorption and light available supplies. The fact that this country is called on for large supplies of gold is taken advantage of by silver dealers to beat down the price of the latter, but after harvest or say on and after July next gold will set back to this country, for Europe will be a buyer of our railroad and other securities and also our surplus cereals. The balance of trade, then, will be largely in our favor, and to meet it gold will have to be sent to this country. English statistics show that India has drawn silver very heavily so far in this year, larger, if anything, than for four years past.

BORAX—Receipts the past week aggregate 693 cts. This will be shipped chiefly to the East by water owing to freights being lower by that route than by land.

LIME—Receipts the past week aggregate 3183 bbls. The market is steady. Considerable lime is sent up north direct.

LEAD—The market continues unsettled, with quotations nominally unchanged, although it is known that a lower figure than we give for pig is accepted by sellers.

TIN—The market is fairly steady. Month after next the increased duty on tin-plate will take effect, but that on pig tin will not go into effect for two years. As tinplate is only about two per cent tin and the balance either iron or steel, the higher duty will not affect pig tin to any extent, if it does at all. London cables to *Iron Age* report that for pig the market is strong, chiefly on brisk demands for near future deliveries. Spot stocks are in strong bands and consumption continues on a large scale.

IRON—The market continues easy under large stocks on spot and to arrive. The Eastern and European markets have an advancing tendency.

COPPER—The market is essentially unchanged. The impression prevails that a quiet movement is going on to concentrate supplies for a bull campaign. Eastern advices report buyers conservative. Lake Superior ingot is quotable at 13½ to 13½ cts. and 12½ cts. for Arizona ingot; over 11½ cts. for ordinary casting copper is realized only on small parcels.

COAL—Imports the past week aggregate as follows: Nantam, 6516 tons; Departure Bay, 9065; Newcastle, N. S. W., 6553; Tacoma, 10,800; Seattle, 6663; Nagasaki, 2065; Coos, 1200; total, 42,962 tons. A cargo of English spot was on the market as low as \$7 a ton. The heavy shipments of English and free supplies arrived keep the market for steam in buyers favor. After a few days suspension, vessels are being dispatched from Australia for this port. It is said that more vessels are offering there for July-August loading for this port. With us the spot and near-by coal market is fairly easy.

Coal and Coke.

SPOT FROM YARD—PER TON.	TO LOAD—PER TON.
Wellington.....	\$10 00 Australian.....
Greta.....	8 50 Liverpool Stm.....
Carillon Hill.....	8 00 Scotch Splint.....

Eastern Metal Markets.

By Telegraph.

NEW YORK, May 14.—The following are the closing prices the past week:

Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday.....	44½	98½	13 75	4 20
Friday.....	44½	98	13 75	4 25
Saturday.....	44½	97½	13 75	4 25
Sunday.....	44½	97½	13 75	4 25
Monday.....	44½	97½	13 75	4 25
Tuesday.....	44½	97½	13 75	4 22½
Wednesday.....	44½	97½	13 75	4 22½

Tin is stronger and in good demand. Lead is steady. It is claimed that copper has a more promising outlook, but at present it is dull. Borax continues to move off free. Iron is strengthening both at home and abroad.

DIVIDEND No. 3 of five cents per share, aggregating \$1500, has been declared by the W. Y. O. D. Mining Co. A cleanup from one month's run of ore from the mine at Grass Valley last Saturday yielded \$5000, not including sulphurets, which go about \$300 per ton. About four tons of ore per day were worked.

Mining Bureau Museum.

Following are among the recent contributions to the museum of the California State Mining Bureau:

From Mr. J. W. Copeland, Specimen of Stromeyerite (sulphide of copper and silver), of Silver King Mine Pinal Co., Arizona.

Medal struck at the U. S. Mint, from bullion produced from Nevada ores, at the Centennial Exposition in Philadelphia 1876, Thos. G. Taylor.

Calcite (Botryoidal), found with Precite at Lone Ranch Chetco, Curry Co., Oregon; and improved folding miners' candlestick, Wernitz patent, Dec. 25, 1888, E. B. Benedek.

Aragonite, Silver Canyon Santa Catalina Island, Los Angeles Co.

Stam, tantalite from Grusen, S. Dakota. Autunite, Black Hills, Werner Saugbutt. Pectolite, Santa Barbara, Dr. S. G. Yates.

Turquoise, Candelaria, Nev., W. H. Shockley. Chromic iron, near Cholame, San Luis Obispo Co., Hutchins & Montgomery.

Copper ore, Whale Mine, Inyo Co., W. C. Chapin.

Fossil shells, Ventura Co. Heike Kani (Face crab), Inland Sea, Japan, Arthur E. Roberts.

Sponge (fine texture), coast of Siberia, Capt. Geo. Ball.

Zinc ore (sphalerite), Silver Canyon, Santa Catalina Island, Los Angeles Co.

Purilite, from Asbestos mines, Thetford, Quebec, Canada, B. E. Syster.

Clay, plastic and refractory, Santa Barbara, I. L. Perry.

Gold quartz, from a ledge in the desert, 35 miles northwest from Mojave, Kern Co., E. P. Marsellus. Severite (hydrous silicate of alumina), Otay ranch, San Diego Co., San Diego Chamber of Commerce.

Gold quartz (rich in fine gold), Florence mine, Leadville, Col., Hans Vogl.

Silver (native, on ore), Continental Chief mine, Leadville, Col.

Gold quartz (showing free gold), Eureka vein, Pine Valley district, San Diego Co.

Tin ingot, smelted from ore of the Temescal mines, San Bernardino Co., J. H. Crossman.

Boulangerite (sulph-antimonide of lead), W. H. Shockley.

Glanconpane (first occurrence noted in California), from Wellets, Mendocino Co., H. F. Finell.

San Francisco Metal Market.

JAMES E. KEELER has resigned his position as astronomer at the Lick Observatory and will occupy a chair in the University of Pennsylvania. The Board of Regents has passed resolutions expressing appreciation of his past services and wishing him future success. W. W. Campbell, instructor in astronomy at the University of Michigan, has been appointed as successor to Prof. Keeler for one year at an annual salary of \$1800. The Lick Observatory had no more active or intelligent young man on its staff than James E. Keeler, and his resignation is to be regretted by all interested in astronomy in this State. His work was always thorough in every way, and he had the respect and friendship of his associates. He was one of the Secretaries of the Astronomical Society of the Pacific and a frequent contributor to its transactions. The Lick Observatory can ill afford to lose such a valuable and thoroughly qualified worker.

STEAM ENGINEERS—An association of the American Steam Engineers, subject to the Supreme Council of the Order, was organized in this city this week with the following officers: Chief engineer, John Oswald; recording engineer, P. L. Stevens; financial engineer, J. M. Zinkle; treasurer, A. Wilson; chaplain, John Farquhar; senior master mechanic, N. B. Ganid; junior master mechanic, C. R. McPherson; inside sentinel, B. J. McShain; outside sentinel, Sidney Ferd.

WHAT CAUSES THE FLAME OF THE ELECTRIC ARC?—The electric arc is composed of a steam of vapor arising from the actual boiling or vaporization of the solid or fused ends of the separated conductors.

Mining Share Market.

Mining shares, so far as the Comstock are concerned, had the dumps the past week, with quite a decline in the prices of those that had made the most decided up move. Persons who give close attention to the workings of the market, and conservatively judge the why and whereof of the moves, were prepared for the setback which took place. Their opinion is grounded upon the work going on in the mines and also the position of shares. They also claim that there can be no doubt but the managers of two or more of the mines have turned the work in their respective mines with the view of making an ore strike, and the preliminary movement to it has been and still is the concentration of stocks at as low prices as possible and then deal them out on the public at higher prices on big ore develops, prospective or actual dividends or on anything else calculated to excite the cupidity of the more credulous. That a fair to large showing of ore can be made to the west in any of the mines is generally conceded by old and experienced Comstock miners, but in which it will be made so as to make a stock deal is an open question, which time can only solve. The setback the past week caused weak bidders and timid dealers to throw their stocks on the market, and as bear points were circulated thick and fast, it is unreasonable to suppose that other outside dealers bought much. At this writing it looks as if the market will advance within the next four weeks to a higher range of prices than has been reached on the present deal.

Mining shares opened this (Thursday) morning fairly firm at a slight advance on last night's closing. The 30 per cent setback this week uncovered quite a line of stocks on margin. The market acts to-day as if it is about bottom, and that much higher prices will obtain soon.

At the East, large speculators, in general, look for more active and higher markets for railroad and other securities this fall. This opinion is based on the outlook being favorable for large crops and good prices, which always create speculation.

Owing to numerous inquiries it has been decided to run, at an early day, a map of the Comstock showing the Comstock lode or White ledge and the Red or west lode. This will convey a good idea to our patrons of the two lodes.

News from the Comstock report two mills are running on Con. Virginia ore, and they also indicate higher battery assays, but whether they will be higher remains to be seen. That they can be advanced up to over \$50 a ton is the current belief among miners. Best and Belcher after "running away" from the ore body, have started for it; probably enough stocks have been bought during the last decline to warrant this move. It is claimed that Sierra Nevada levied an assessment to get the public to sell stock, and afterward show up the ore in the west. The work going on in Ophir and Union is quite important. Gould & Curry continue to send ore to the mill; the assays are lower than private advices report. In Hale & Norcross they are opening out new levels. In Savage, they have started an important crosscut on the 1100-foot. Unless the work is stopped they will run into rich ore. In Con. Imperial and Challenge a joint crosscut is being run for ore known to exist to the west. The north drifts being run by Confidence and Challenge ought to open up several very important levels for future work. In Crown Point, Belcher, Kentuck and Yellow Jacket the prospecting work being done ought to develop into something quite important in the near future. Overman, Chollar, Con. Imperial, Chollar and Savage continue to send their regular quota of ore to mill. The battery assays go from \$18 to \$23 a ton.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

SINCE the 1st of January 62 mining companies have paid dividends amounting to \$4,846,270.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING MAY 5, 1891.

- 451,550.—SHEET METAL ROOFING—J. C. Bayer, Portland, Or.
451,803.—LADDER—G. T. Campbell, S. F.
451,648.—TRACTION ENGINE—N. L. Darling, Benicia, Cal.
451,857.—CABLE GRIP—J. J. Graff, S. F.
451,668.—NIPPERS—D. A. Hamilton, Heppner, Or.
451,712.—WATCHMAKERS JEWEL SETTING CUTTER—A. Hartung, Nevada City, Cal.
451,594.—BORING MACHINE. A. M. Jewell, S. F.
451,595.—BORING MACHINE. A. M. Jewell, S. F.
451,765.—VALVE GEAR FOR ORE STAMPS—C. Kendrick, Jr., Nevada City, Cal.
451,608.—HORSE TAIL HOLDER—J. W. Lindsay, Fresno, Cal.
451,839.—ANIMAL TRAP—John Picard, St. Paul, Or.
451,530.—WASHING MACHINE—Z. W. Shields, Harrington, Wash.
451,531.—NEUTRALIZING SULPHO-CHLORINATED OILS—A. Sommer, Berkeley, Cal.
451,626.—STRATIFIED BRICK—L. A. Steiger, San Jose, Cal.
451,783.—SHINGLE—R. P. Taylor, Gold Hill, Nev.
451,655.—VETERINARY INHALER—H. T. Welch, San Jose, Cal.
451,544.—RAILWAY RAIL COUPLING—J. T. Wicker, Sprague, Wash.
451,586.—INSULATE ELECTRIC CONDUCTOR—J. B. Williams, Oakland, Cal.
451,587.—INSULATE ELECTRIC CONDUCTOR—J. B. Williams, Oakland, Cal.

The following brief list by telegraph, for May 12, will appear more complete on receipt of mail devices:

California—San Francisco: Peter Barclay, street-railway rail and pavement; Nora M. Barrett, gas engine attachment; Charles E. Naylor, safety-grip brake for cable cars; Franz Smith, door manipulator. Oakland—James L. Crittenden, drain pipe for buildings; Frank A. Huntington, power street-paving machine; Jas. B. Williams, treating conductors. Nevada City—Amelia Fogeh, fruit-picker. Alameda—Adolph Lajeunesse, weather strip. Oregon—Portland: Craig H. Murray, bedstead, tablet. Washington—Seattle: Emma C. Hudson, house-door letter box; Wm. R. Phillips, hydraulic air-compressor. Spokane Falls—John McKinnon, clothes-drier. Montezuma—Michael Reilly, rotor stop and driving cable.

Notes.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

VETERINARY INHALER.—Henry T. Welch, San Jose. No. 451,655. Dated May 5, 1891. The object of this invention is to provide an inhaler which is specially adapted for horses and which by reason of its construction can be readily and securely applied in a way that will not inconvenience the horse. The inhaler consists of a hollow medicine-receptacle having top perforations and bent to fit the upper lip of the horse below the nostrils.

TRACTION ENGINE.—N. L. Darling, Benicia, assignor to Benicia Agricultural Works. No. 451,648. Dated May 5, 1891. This invention presents certain features of novelty, among which may be noted a compact form of boiler engine, bed-piece, driving and steering wheels, power being transmitted from the engine to the driving wheels by means of sprocket wheels and driving chains in place of the gears which are usually employed. The driving wheels are of very large diameter, and are specially constructed with a view to strength. The bed-piece of the engine is peculiarly constructed so as to make it very compact, at the same time providing sufficient room for the eccentrics and valve gear without unduly lengthening the engine shaft. A peculiar clutch mechanism is employed to connect the engine shaft with its driving sprocket wheel, or disconnect it therefrom, and a suitable equalizing gear is fitted to the counter-shaft from which the power is transmitted to the two driving wheels. Another peculiarity of the engine is in the construction of a truss frame whereby great strength and rigidity is effected, and through the agency of which the draft bar is connected with the engine at a point low down, and in such a manner that a heavy draft tends to hold the engine down upon the ground instead of lifting it up.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

EAST OAKLAND RAILROAD CO., May 9. Capital stock, \$250,000. Directors—E. C. Sessions, C. E. White, E. P. Vandercook, R. F. Crist and W. R. Melvin.

PACIFIC COAST AMUSEMENT DEVICE CO., May 9. Object, to introduce, rent and sell rotary toys, amusement devices, fortune-telling machines, nickel-in-the-slot machines, and other kinds of toys. Capital stock, \$100,000. Directors—James W. Hartley, Achilles Ross, Shaller Howard, W. R. Gouldberg and Alfred Bouvier.

BELDING CONS. M. CO., May 13. Location, Esmeralda Co., Nev. Capital stock, \$5,000,000. Directors—W. J. Sutherland, H. Zading, G. R. Wells, N. T. Spencer and Chas. Hersfield.

THE Gould & Curry Mining Co. has received \$11,406.03 as the net proceeds of amalgam from 1120 tons of ore worked at the Nevada mill, which was sold to the Carson mint.

Assessment Notices.

GRAY EAGLE MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Placer County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 3d day of April, 1891, an assessment, No. 23, of Three (3) Cents per share, was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 11, No. 303 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 5th day of June, 1891, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.
A. W. BARROWS, Secretary pro tem.
Office, Room 11, No. 303 California Street, San Francisco, California.

MARSHUTZ & CANTRELL, Sole Manufacturers.

Send for Circulars and Price List.

MARSHUTZ & CANTRELL.

The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture. We guarantee purchasers of this form of Giants against all costs, expenses or damages which may arise from any adverse suits or actions at law. We are further prepared to furnish Single-Jointed Giants when required. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent on application.

JOSHUA HENDY MACHINE WORKS, 39 to 51 Fremont St., San Francisco.

**SQUARE FLAX PACKING.**

MANUFACTURED FROM STRICTLY FIRST-CLASS FLAX AND PURE LUBRICANTS. HAS NO SUPERIOR for all Hydraulic Work.

W. T. Y. SCHENCK—Dear Sir: We find your "Red-Cord" Square Flax Packing the "Boss." Yours truly,
J. R. LANE, Secretary.

The red cord runs the entire length. Put up in boxes of 20 feet, or coils of 60 to 80 lbs. For sale by all dealers. W. T. Y. SCHENCK, Sole Manufacturer, 222 and 224 Market Street, San Francisco, Cal.

Adamantine Shoes and Dies—AND—**CHROME CAST STEEL**

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by **CHROME STEEL WORKS, Brooklyn, N. Y.**

A. T. DEWEY } Dewey & Co.'s Scientific Press Patent Agency { ESTABLISHED
W. B. EWER. }
Geo. H. STRONG. } 1860

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 230 Market St., S. F.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs;" for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if need be. Circulars and testimonial letters furnished on application.

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont Street, San Francisco, Cal.

(PATENTED.)

Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

Original Empire Mill and Mining Company,
Principal Office, 401 California St., cor. Sansome, S. F.
Location of Works, Grass Valley, Nevada Co., Cal.

GRASS VALLEY, NEVADA CO., CAL., NOV. 10, 1885.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.

GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID McKAY, JR.,
(Signed) Sup't North Star and Original Empire Mining Co.

N. B.—When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

Retorts and Melting Furnaces.

Various styles and sizes of retorts are in use in the mills of this coast. Gold mills require much less retorting capacity than silver mills of the same size. Many small gold mills use the sample "pot" retort, shown in the cut, which is portable and can be used on an ordinary forge, or in a temporary furnace prepared for the occasion. It is, however, more economical and satisfactory to have all retorts placed in permanent settings.

The accompanying cuts show the smaller pattern of cylinder retorts and melting furnaces combined in one setting, such as are used in gold mills and small silver mills. After being thoroughly strained, the amalgam is placed in the retort in suitable iron pans. The retort is then sealed except the vapor discharge pipe, the open end of which is placed under water in the condensed tank. A water jacket condenser is fixed to and surrounds the vapor pipe through a continual supply of cold water flows condensing the vaporized quicksilver while passing through it to the settling tanks.

The time required to retort a charge of amalgam depends largely upon circumstances, and varies from one to four hours.

Other cuts on this page represent the Standard 14x60 "oil" retort embodying Mr.

Boss' improvements, by which the usual objectionable bearing bars are dispensed with, the retort having a series of brackets cast on the sides which rest on the brick walls, exposing the entire lower surface of the retort to the fire, and insuring a uniform distribution of heat to all parts of the retort. The bands which surround the retort prevent warping.

Its supporting brackets are placed centrally, so as to admit of turning the retort over and using both sides, thus increasing its life materially. These forms of retorts are manufactured by the Riedon Iron Works of this city.

Perret Single Reduction Electric Hoist.

The introduction of the Perret slow-speed multiplier motor, a year or so ago, marked a new era in the history of electric power, and the remarkable success attained by this motor has resulted in overthrowing the very general opinion which at that time prevailed, that slow-speed multiplier motors were impracticable. These motors have since been applied to almost every conceivable kind of work requiring single reduction or direct gearing, and have proved a decided success.

We illustrate, as above, an Electric Dock Hoist, brought out several months since by the Elektron Mfg. Co. This is a piece of machinery

PERRET SINGLE REDUCTION ELECTRIC HOIST.

every where single reduction is particularly desirable, on account of the saving in space, noise, friction and consumption of current. The motor is a 15-horse power Perret multiplier, making 450 revolutions per minute, geared by a gun metal pinion to a 38-inch gear, on the drum shaft of hoist. The drum is one foot in diameter, giving a speed on hoisting rope of a little over 200 feet per minute.

The motor is shunt wound, and drives the gear-wheel at a constant speed, which may be increased, if desired, by the introduction of resistance in the field circuit. By depressing the hand lever, the hoisting drum is forced against a friction device, revolving with the gear-wheel and lifts the load, its speed varying with the pressure on the lever. To lower the load the foot lever is depressed and the hand lever raised. The whole machine is very compact and simple, and is built to stand rough dock usage. The motor is water-proof, and has all the latest improvements.

The American Order of Architecture.

We present herewith a cut of a column to show the advancement we are making in local art and architecture. The column is an exact reproduction of those in the lower vestibule of the capitol at Washington.

These columns were eight in number and small, being only eight inches in diameter, and stand in the Capitol beneath the office of the United States Marshal. They constitute the first bold stride toward forming for ourselves an ornamentation peculiarly in keeping with our new and vigorous government.

These diminutive pillars have stood alone in their unnoticed portion of the Capitol—the only specimens of a purely American order of architecture in existence—until now Col. Jackson has reproduced them at his Springs in a much more pretentious and magnificent form.

His columns are 12 in number, 24 feet in height and two feet in diameter. Each column is composed of a cluster of Indian corn-stalks bound together so that the joints of one stalk stand slightly above the preceding one; thus by the recurrence of the joints in the seven divi-

sions of every stalk, a spiral effect is produced. The capitals are composed of ears of corn with the half-open husks, displaying the corn which stands out at an angle to the main column.

CYLINDER RETORT FOR SMALL MILLS.

IMPROVED CYLINDER RETORT WITH BOSS' IMPROVEMENT.

Common Names for California Trees.

[Written for the Press by J. G. LEMMON]

There is much confusion in the use of common or vernacular names for our forest trees.

Our most familiar species have been given each a dozen or more names, while in many instances the same name is applied to a dozen or more species. These names conferred by the early settlers are often based upon some local feature or passing fancy, which, when the subject of them is better known, become totally inappropriate or viciously misleading. It is desirable to correct, if we may, this erratic treatment of our trees.

As long ago as 1878, when the distinguished botanists, Sir Joseph Hooker, Drs. Asa Gray, George Engelmann and O. C. Parry were making a hurried examination of the forests of the Northwest, the writer hasought these great authorities to select from the host of names given loosely, to our trees, one the most appropriate for each of our species, and to sanction its exclusive use thereafter.

One of the savants regarded the proposition as a good one; another promised that it should be done before they separated; a third thought they had not time then to perform so important a work, while the fourth declared that such a thing could never be accomplished. "The lumbermen, hunters and travelers," he said, "will always be giving names to objects however bad they may be in themselves, or misleading they might become."

Nothing came of my suggestion, and the confusion of names has increased apace, owing to the increased attention given to our trees by this visit of the Eastern scientists and by later publications.

In the extended articles of the Botanists' Reports, included in the 2d and 3d Biennial Reports of the California State Board of Forestry, an attempt is made while elaborating the great class of *Coniferae*, or cone-bearers, to bring order out of the confusion of names, by selecting the least objectionable name in common use; or, in a few instances, coining a new one for each of the kinds of trees, and then using this one habitually in subsequent discussions, hoping thereby to set the example of uniformity and precision.

This effort has been so much commended of late that I yield to an urgent request to publish abbreviated descriptions of our forest trees, just sufficient to bring out the characters upon which are based the vernacular names for the groups as well as species. The following descriptive list has been prepared for our largest family of trees—the pines. Later, it may be followed by a similar list of the rest of the cone-bearing trees.

Descriptive List of Groups and Species of California Pines.

CLASS I. SMOOTH-CONED, SHORT-LEAVED WHITE PINES.

Cones smooth, devoid of protuberances, prickles or hooks; seeds large, leaves in 5s. Wood usually lighter-colored, softer and less resinous than that of the other class. Four species in two groups of a pair each.

GROUP 1. LONG CONED, LUMBER PINES.—Cones long, narrow, cylindrical, 8 to 22 inches long and 1 to 4 inches thick, on long stems becoming pendent and breaking at maturity. Trees usually very large with grayish, finely checked bark, large and long upper bearing limbs and light-green foliage.

No. 1—*Pinus Lambertiana*, Dougl., "Great Sugar Pine."—Trees of the largest dimensions, 120 to 300, or, favorably situated, 250 to 300 feet high and 10 to 20 in diameter; scattered among other trees of the Coast and Sierra mountains at middle elevations. Cones very long, 10 to 22 inches long—the longest known.

No. 2—*Pinus monticola*, Dougl., "Mountain Pine."—Smaller, lighter harked trees than the preceding in sub-alpine regions of the Sierra, but northward in Oregon and Washington found at lower elevations; cones narrow, 6 to 12 inches long; scales thin, weak, reflexed at maturity.

GROUP 2. SHORT CONED, ALPINE PINES.—Dwarfed, often depressed trees forming the upper fringes of the forests on the Rocky Mts. and the Sierra Nevada.

No. 3—*Pinus flexilis*, James., "Limber-twig Pine."—Small or depressed trees of the Rocky mountains and a few on the peaks of certain mountains in the Southern Sierra.

No. 4—*Pinus albicaulis*, Engel., "White-bark Pine."—Very white harked, often depressed trees forming the timber line on certain peaks of the Sierra. Cone globose, set close upon the short, stout, erect, white, annual stems.

CLASS II. ROUGH-CONED, DIVERSE-LEAVED, PITCH PINES.

Cones rough, armed with conspicuous knobs, prickles or hooks. Wood usually darker, harder, more resinous than that of the first class. Fourteen species in two sections of two groups each.

SECTION A. SUB-TERMINAL, MOSTLY DECIDUOUS-CONED PINES.—Cones arising near the terminal leaf-bud, deciduous at maturity. Eight species in two very unequal groups.

GROUP 3. COHERENT-CONED, SHORT LEAVED, CLOSE-GRAINED PINES.—Cones small, at maturity separating from the stem entirely. Three diverse pairs of species.

1st PAIR. OBLONG-CONED, PLUME PINES.—Cones oblong, cylindrical, 3 to 5 inches long, pendent from the long, plume-like brancholets;

leaves in 5s. Sub-alpine trees of the Rocky mountains, with a few trees only on the Sierra.

No. 5—*Pinus Balfouriana*, Jeff., "Fox-Tail Pine."—A few trees in sequestered nooks near Shasta and in the vicinity of Mt. Whitney. Cones with very small prickles.

No. 6—*Pinus aristata*, Engel., "Bristle-Cone Pine."—Similar but smaller trees on a few peaks of the Southern Sierra, but chiefly in Arizona, New Mexico and Colorado. Cones with long, conspicuous, bristle-like prickles.

2ND PAIR. GLOBE-CONED, NUT PINES.—Cones sub-globose $\frac{1}{2}$ to 2 inches thick; scales few; very protuberant, without prickles, widely opening at maturity, loosely holding the large, delicious seeds.

No. 7—*Pinus monophylla*, Tor. and Frem., "Single-Leaf Pine."—Small, branching trees of the Great Basin, the eastern slopes of the Sierra, and the Tehachapi mountains; leaves solitary, terete, pungent-pointed; seeds, large, hard-shelled.

No. 8—*Pinus Parryana*, Engel., "Parry Pine."—Small trees in the peninsula of Lower California, with a few specimens extending into San Diego Co., California. Cones smaller than the preceding, with soft-shelled seeds; leaves in 5s.

3D PAIR. THIMBLE-CONED, THIN-BARK PINES.—Cone very small, 1 to 2 inches long, strongly declined; leaves in pairs. Trees with exceptionally thin bark and small cones.

No. 9—*Pinus contorta*, Dougl., "Scrub Pine."—Very small, scrubby trees, on and near the northwest coast of California and Oregon, the very small cones often remaining on the trees for many years.

No. 10—*Pinus Murrayana*, Belf., "Tamarack Pine."—Tall, slender trees in wet, sub-alpine swamps of the Sierra and northward; also in the Rocky mountains. Cones ovate-conical, $\frac{1}{2}$ to $\frac{3}{4}$ inches long. Trees usually discharging pitch or gum. Bark only one-fourth to one-half inch thick. Wood tough and light.

GROUP 4. BROKEN-CONED, LUMBER PINES.—Cones breaking away at maturity from the short stem by an irregular, transversal fracture within the base. They are of medium size, ovate-conical, 4 to 8 inches long, and half as broad at base; leaves in 3s, 5 to 8 inches long. Large trees, with thick, deeply fissured bark, and yielding lumber of great value. Trees widely distributed at middle altitudes.

No. 11—*Pinus ponderosa*, Dougl., "Yellow Pine."—Trees of the largest size 200 to 300 feet in height; the largest often 250 to 300 feet high and 5 to 15 feet thick; bark in the typical form, yellowish or whitish, mostly very thick and deeply fissured into large plates; cones, conical-ovate, 2 to 5 inches long; male flowers, long and flexuous. The broken branchlets exhale an odor of turpentine.

Var. (a) *nigricans*, "Brown-bark Pine."—Trees of medium size flourishing usually in moist situations than other forms and longer retaining their lower limbs; sap-wood usually of many layers; cones, largest of the species, 3 to 6 inches long.

Var. (b) *Benthaimana*, "Foothills Yellow Pine."—Medium-sized trees in the coast mountains and Western Sierra foothills, usually spire-shaped; cones, smaller and narrower than the preceding.

Var. (c) *brachyptera*, "Southern Yellow Pine."—Trees of Northern Arizona and New Mexico; cones, small, ovate, 2 to 4 inches long.

Var. (d) *scopularum*, "Rocky Mt. Yellow Pine."—A small, spire-shaped tree of the Rocky Mts.; leaves often in pairs and remaining on the limbs several years.

No. 12—*Pinus jeffreyi*, Mur., "Black Pine."—Chiefly distinguished from the *ponderosa* species (with which it is often associated) by the trees attaining usually more elevated regions, and having darker, finer checked bark; the young branchlets and leaves are colored by a whitish powder; also when broken they exhale a pleasant, aromatic odor, not one of turpentine; cones, large, 6 to 10 inches long, ovate, with strong prickles.

Var. (a) *deflexa*, "Red-bark Pine."—This form constitutes one of the principal timber trees of the high Sierras, notably near Truckee. The bark is usually reddish-brown, thick, coarsely checked by many lines, especially toward the top of the tree; cones, large, 6 to 10 inches long.

Var. (b) *peninsularis*, "Peninsular Pine."—On the San Rafael mountains of Lower California; bark, grayish-brown, thick, deeply furrowed; cones, remarkably abundant and large, 6 to 8 inches long.

Var. (c) *ambigua*,—A tree of the lake region of Western Montana, "with purple cones and long glaucous foliage."

SECTION B.—LATERAL, MOSTLY PERSISTENT-CONED, LONG-LEAVED PINES.—Cones arising laterally, i. e. along the bearing stems, usually at some distance from the apex; mostly not falling at maturity, but persisting and, either becoming inclosed by the later layers of wood, or the peduncle is stretched and at length broken by the enlargement of the tree, while the cone is often carried onward confined in the bark, leaving a channel behind it to the heart of the tree. Leaves large and long, 6 to 12 inches. Six species forming a pair of trios, or groups.

GROUP 5. HEAVY, SPINE CONED, LONG-LIMBED PINES.—Cones of the heaviest, largest and hardest description on long, stout spreading peduncles, opening at maturity, but often remaining until forced off by the enlargement of the tree. Scales of the cone very large and thick, often terminating in long, stout, curved

spines or hooks; seeds very large, black, thick-shelled. Leaves in 3s or 5s, very large and long, 8 to 14 inches. Picturesque trees remarkable for their usually divided trunk or very long limbs and for their heavy, spine-bearing cones.

No. 13—*Pinus Coulteri*, Don., "Big-Coned Pine."—Trees of medium size, with dark green, abundant three-leaved foliage; composed of the largest and longest pine leaves known, 8 to 14 inches long. Cones elongated, elliptical, of matchless size and weight, 15 to 20 inches long and often weighing five to eight pounds. The outer hooks are often two to four inches long, and curved like a nail. Trees of limited range in the Southern coast ranges and San Bernardino mountains.

No. 14—*Pinus Sabiniana*, Dougl., "Gray-Leaf Pine."—Usually small, round-headed trees of the hot, sloping foot hills with divided trunks, and scant foliage of grayish color, all but the leaves of the season dropping downward, or early falling away. Cones broadly ovate, weighing 2 to 5 pounds, armed with stout, short hooks; seeds very large $\frac{1}{2}$ to $\frac{3}{4}$ inch long, with a thick, narrow wing. Leaves in 3s.

No. 15—*Pinus Torreyana*, Parry, "Torrey Pine."—A few small trees not to exceed a few hundred in all; buffeted, often prostrated by the ocean winds at Del Mar, San Diego Co., with a few on Santa Rosa Island. Leaves in 5s, very large and long, 8 to 12 inches. Cones broadly ovate, 4 to 6 inches long, weighing 1 to 2 pounds, and armed with short, stout spines.

GROUP 6. CLOSE-CONED, SLENDER PINES.—Cones in verticils or clusters, usually strongly declined, and gibbous; usually long-persistent, and remaining long-closed, holding the seed. Small trees mostly crowded into dense groves, hence tall and slender; maturing fruit when quite young. Leaves in 3s or 2s.

No. 16—*Pinus insignis*, Dougl., "Monterey Pine."—Beautiful trees on Point Pinos near Monterey, and abundant in cultivation. Leaves in threes.

Var. (a) *radiata*, "Spreading-Cone Pine."—The large-coned form near Monterey bay.

Var. (b) *levigata*, "Nearly smooth cone Pine."—Cone small, nearly smooth. Trees on the outskirts of the forest farthest from the ocean.

No. 17—*Pinus tuberculata*, Gordon, "Knob-Coned Pine."—Usually small, early bearing, slender trees on sunny slopes of the Northern Sierra, and rarely on the coast ranges. Cones strongly declined, narrow and pointed, 3 to 7 inches long. Remaining on the trees and unopened for an indefinite number of years. Leaves in 3s.

No. 18—*Pinus Muricata*, Don., "Prickle-Coned Pine."—Small slender trees usually in swampy places along a limited portion of the coast range, mostly northward from San Francisco. Cones clustered, ovate, 2 to 3 inches long with small, sharp, persistent prickles. The cones have been known to remain unopened for 20 to 30 years, then to release good seeds. Leaves in pairs, usually long, 3 to 6 inches.

The Stanford University.

Announcement is made by circular that the Stanford University will open for students October 1, 1891. For the first year, chairs will be established, and instruction will be given in the following lines of work: Mechanical engineering, civil engineering, mathematics, physics, chemistry, geology, botany, zoology, physiology, philosophy, ethics, history, political science, English language and literature, German, French, Latin and Greek.

The work of the University will begin with the freshman class. For admission to this class, the candidate must be at least 16 years of age, and must pass a satisfactory examination in the subjects specified in the circular, copies of which can be had by addressing President David S. Jordan, Menlo Park, Cal. The following announcement is made of expenses:

Tuition in all departments of the University will be free. Board will be offered at cost in the dormitories. The price fixed at present for board in Madrono Hall is \$3 per week. Rooms with light, heat and attendance are offered at \$1.50 per week for each person, if two occupy one room; \$3 per week, if occupied by one person; but single occupancy will not be permitted if the rooms are needed by other students. Washing will be charged at cost. The expenses of the student in Madrono Hall need not exceed \$200 for the year, exclusive of clothing and railway fares. The accommodations for young women will, at the first, be limited, but an effort will be made to provide suitable rooms for those who may enter the University.

President Jordan is now at the East, but will be at Menlo Park after June 10.

DUTIES ON COAL.—A decision concerning duties on coal has been received from the Board of General Appraisers at New York. R. Dunsmuir & Co. Imported by the steamer Costa Rica a cargo of bituminous coal screenings. Duty was assessed at 75 cents a ton of 2240 pounds, which is the rate prescribed for bituminous coal in paragraph 432 of the McKinley Act. The point claimed by the appellants was that the screenings would pass through a half-inch screen, and that, therefore, the duty should have been assessed at 30 cents a ton under the terms of the same paragraph. It was found by the Board of General Appraisers that 90 per cent of the coal would pass through a half-inch screen. The Board decided in favor of the protest of the importers.

San Diego Mines.

The San Diego Union says: Several thousand dollars in gold bullion were brought in from Julian on Saturday, and placed in the banks.

Work on the Stonewall mine is still in progress. "Dead work" is being prosecuted systematically. There is a great deal of unexplored ground in the Stonewall claim, to say nothing of the prospects for new mineral veins on the grant aside from the Stonewall. A number of good veins are now known, and there is little doubt that intelligent prospecting will discover others of great value, in the vicinity of the Stonewall vein.

As a matter of interest in connection with mining generally, it may be well to state that in the month of April, 40 gold, silver, copper and quicksilver mining companies declared dividends aggregating \$1,315,460, and that since January 1st, 62 companies have paid \$4,846,270.

The High Peak.

At the Helvetia mine at Julian, a force of 35 men is now employed. The shaft is down 200 feet, and has but 25 feet more to go until it will have reached the level of the deepest old workings, which are some distance away and flooded with water to a depth of 200 feet. When work ceased in the mine some years ago, a good body of quartz was left in the bottom of the mine, which carried considerable gold. When this shoot is reached it will supply the mill continuously with quartz for a long time. The rock being crushed at present from the High Peak is hauled to the Helvetia mill, a mile or so distant. Both the High Peak and Helvetia mines and the mill are the property of Mr. Havermale of San Diego. The owner has every confidence in his mine, and is doing the development work in a miner-like fashion, as though he anticipated a long period of prosperity, and not a little boom of a day.

It is understood from persons who came down from Julian Saturday that Mr. Lane, one of the Pomona representatives of the Gold King company, is about to assume charge of the mines of the company.

The Pine valley district, where the rich strike was recently made, is situated about 20 miles southeast of Julian, and is said to be a very promising district. If very much \$2000 rock is found, it won't be very long before it will be pretty thoroughly investigated.

Are There No Silver Mines?

It may seem strange that so few silver mines are known or heard of in San Diego county. This fact is not positive evidence that there are no silver veins here. Those who inhabit the western portion of the county are essentially agriculturists and not a mining people; even near Julian about as much attention is given to farming as to mining. The fact is the miners in Southern California are gold prospectors and are not well posted in silver ore, and consequently fail to look for or notice "silver indications." There are no better searchers for gold prospects anywhere, but the drawbacks to silver prospecting are so numerous that but few mines of silver have been found in this county. There is little doubt there are good silver deposits back in the mountains, but they have never been prospected intelligently, if at all.

PUBLISHING MINING NEWS.—The Georgetown (Colo.) Courier, says: The reporter lives in a mining town. One of his pleasantest duties is to note the prosperous strikes of the miners when fortunate, and sympathize with them when they meet with ill luck. Of course all the mining news must be reported, and of course no individual miner must be mentioned. When the mining column is full, then the mine owner howls and wonders why in thunder that item was published. You are told that it is all wrong, but you can't get it right under any circumstances—because you can't get facts to make it right. And if the mining column has a few general items, its darn the newspapers anyway—there's nothing in them. Now mining news is the only general news that advertizes this county. If there is plenty of live, accurate mining news, it attracts capitalists. We can't grow wheat, we can't grow corn, but we are developing the best mines in the State. There is a lot of unprospected territory to be gone over, but it will never be touched so long as nothing is said about mining. It is a selfish principle to keep everything on the dead quiet. Men are glad to hear of other men's luck. It encourages them. It shows that something is going on. But ye patient reporter will have his revenge. He will give good, live, reliable mining items where he can. Where he cannot he will write his brainpan and say what ought to be if he can't say what really is. And ye mining men who get frothy at the mouth can go to the chief editor and tell the facts so the public will get at the truth at last. There are no flies on ye reporter at any season. There are no flies on some of ye mining men—because fly time has not yet come.

By the application of chloride of antimony a beautiful violet color is imparted to brass work. The brass should first be made perfectly clean and heated until water will steam off it without hissing.

SUGAR ON INCrustATION.—Recent experiments with sugar as a preventive for incrustations of steam boilers are reported as giving very satisfactory results.

Working, Rights of Way and Drainage of Mines.

The following law was passed at the recent session of the Legislature of this State:

SECTION 1. Whenever any mine owner, company or corporation shall have performed the labor and made the improvements required by law for the location and ownership of mining claims or lodes, such owner, company or corporation shall file or cause to be filed, within thirty days after the time limited for performing such labor or making such improvements, with the County Recorder of Deeds of the county in which the mine or claim is situated, an affidavit particularly describing the labor performed and improvements made, and the value thereof, which affidavit shall be prima facie evidence of the fact therein stated. Upon the failure of any claimant or mine-owner to comply with the conditions of this Act in the performance of labor, or making of improvements upon any claim, mine or mining ground, the claim or mine upon which such failure occurred shall be open to relocation in the same manner as if no location of the same had ever been made. But if, previous to relocation, the original locators, their heirs, assigns or legal representatives, resume work upon such claim, and continue the same with reasonable diligence until the required amount of labor has been performed or improvements made, and the required statement of accounts and affidavits filed with the County Recorder, then the claim shall not be subject to relocation because of previous failure to file accounts. Upon the failure of any one of the several co-owners to contribute his portion of the expenditures required hereby, the co-owners who have performed the labor or made the improvements may, at the expiration of the year, give such delinquent co-owner personal notice, in writing or by publication in the newspaper published nearest the claim, for at least once a week for ninety days; and if, at the expiration of ninety days after such notice in writing or publication, such delinquent shall fail or refuse to contribute his portion of the expenditures required by this section, his interest in the claim shall become the property of his co-owners who made the required expenditures. A true copy of such notice, together with an affidavit showing personal service or publication, as the case may be, of such notice, when filed or recorded with the Recorder of Deeds of the county in which such mining claim is situated, shall be evidence of the acquisition of title of such owners. Where a person or company has or may run a tunnel or cuts in good faith for the purpose of developing a lode, lodes or claims owned by said person or company, or corporation, the money so expended in running said tunnel shall be taken and considered as expended on said lodes or claims, provided further that said lode, claim or claims shall be distinctly marked on the surface as provided by law.

SEC. 2. All mining locations and mining claims shall be subject to a reservation of the right of way through or over any mining claims, ditches, roads, canals, cuts, tunnels and other easements for the purpose of working other mines, provided that any damage occasioned thereby shall be assessed and paid for in the manner provided by law for land taken for public use under the right of eminent domain.

SEC. 3. This Act shall take effect immediately.

THE FAHRUMP MINES.—The *Reno Journal* says C. R. Glass, formerly of the United States Surveyor General's Office here, arrived yesterday from the new mines in the southern part of Nye county. These mines were discovered early last winter by George Montgomery, who left San Andreas, California, with a party of five prospectors, fully equipped, to prospect southwestern Nevada and search for the mythical Breyfogle mine. In the northwest end of the Washington Mountains, which skirt one side of the Fahrump Valley, the party discovered gold-bearing quartz. They located several leads, some of which contain galena and silver-bearing ores, but all rich in gold. The ledges are from five to ten feet wide and the mineral belt in which the ledges are situated is at least six miles long and from one to two miles wide. A new district, named Montgomery in honor of the discoverer, has been organized, and when Mr. Glass left, there were about 100 men and one woman in the camp. Water is carried in canvass bags, and packed on donkeys' backs, four miles from the nearest springs. Nut pine timber, good for fuel, is abundant within four or five miles of the mines, and white pine, suitable for timber, abounds about 20 miles from Montgomery. The nearest postoffice is Ivanpah, California, 80 miles away, but a postoffice will be established at Montgomery in a few weeks. Much of the agricultural land in Fahrump Valley has been taken up by Californians under the land laws of Nevada, but there is plenty of timber land to be had at the Government price, \$1.25 per acre.

A PAYING GOLD MINE.—The gross yield and the dividends of the Idaho Mining Company have always been a subject of dispute, says the *Grass Valley Tidings*. Figures purporting to be correct have frequently been published. Reliable authority, however, places \$11,250,000 as the gross yield and \$4,350,000 as the aggregate of the dividends, and these figures are as nearly right as can be obtained without reference to the books and an exercise in addition. The dividends are 253 in number.

Daniel Best.

The necessity of labor-saving machinery, especially of agricultural implements, and also the opportunity for rich reward, has stimulated the best talent and brightest minds in devising and inventing implements and machinery suited to our condition and environment. Among the men who have ministered to this demand is the subject of this sketch, Mr. Daniel Best of San Leandro. He is a native of Ohio and a descendant from that noted ancestry that settled in Ohio and Kentucky with Daniel Boone. His occupation was a farmer. In 1859 he went to Portland, Oregon, and led a roving life, alternating as a prospector and laborer. At the age of 21, he commenced carrying slabs at a sawmill, and in less than six weeks he was foreman and manager. Shortly afterward he was the subject of a mining fever, and made a venture in the mining region of the Blue mountains of Idaho and Oregon.

He commenced manufacturing lumber with a whip saw, but soon devised a plan to build a sawmill out of the waste iron that had been scattered on the plains by emigrants. With a tool-chest containing one saw, broad-ax, square and augur, he succeeded in building a sawmill that could turn out 1200 feet of lumber per day. Mr. Best afterward ran a sawmill in Washington Territory, and while there met with a severe accident that induced him to come to California, settling in Sutter county.

He saw the necessity of portable cleaners for

DANIEL BEST, THE CALIFORNIA INVENTOR AND MANUFACTURER.

grain, and designed and invented one, a half-interest of which he sold for \$5000 to Mr. L. D. Brown, the joint interest of which was sold for \$32,000 afterward. He organized the Marysville Mining Co., and spent two years in Oregon up to 1876.

In September, 1885, he bought out the San Leandro Agricultural Works, Alameda county, and entered largely in the manufacture of agricultural implements, principally grain-cleaners and combined harvesters. During the last four years he has given a great deal of attention to the building and improving the Remington traction engine. With his improvement, for which letters patent have been granted him, he has succeeded in making the traction engine a necessity to our large ranchers and lumber-men. Of these traction engines there are now 28 in actual use, and in every competitive trial the Remington has been awarded first premium. His latest invention is a gas engine that has given unqualified satisfaction.

Mr. Best is a genial, modest and reliable citizen, prosperous in business, and enjoys a high reputation as a man of veracity and integrity. He has been blessed in his domestic relations, and at his hospitable home is surrounded by a most estimable wife, who has shared his fortune in adversity and prosperity, and six promising children. He is an honored member of the Ancient Order of United Workmen.

He is possessed of a high mechanical talent, and may be properly termed an inventive genius. The results that have followed his inventions and the success of his labor-saving machines and agricultural implements entitle him to rank with other great American inventors, such as Whitney, Singer and McCormick. Our artist has made a correct likeness of Mr. Best, whose name has become noted as the sagacious inventor and successful manufacturer of agricultural implements and traction engines.

A Proposed Mining Tunnel.

The Tintio (Utah) *Miner* says: While wandering around seeking stray items, the first of the week, we dropped into Christensen & Burch's office, and deliberately stole what we think to be an item that is to be of vast importance to Enreka and Tintio. Spread out upon the table before Mr. Christensen was a map and profile of the big tunnel to be run by California capitalists through the mountains southeast of Enreka. This tunnel is to start away east among the iron placers, and runs for a distance of about 5000 feet in the direction of a little west of South, passing close to the northern end line of the Spy and also the Slonx group; then it changes its course and runs a little more west of south for a distance something over 6000 feet. In this last course it passes through the northern part of the Mammoth and southern part of the Centennial-Enreka company's property, about 700 feet southerly from Enreka peak. In crossing the big Mammoth mountain, though it does not go under the summit, it has a depth of 1725 feet below datum line, and when it passes the Enreka peak, which is 1700 feet above the tunnel line, though it passes about 700 feet south of the same, it will have a depth of from 1150 to 1250 feet. The object of the company constructing this enterprise is to furnish an avenue, or more easy way for the numerous mines through which it passes, to get their products to the surface, and we understand

worked on sound business principles, as mining is an industry which is now getting to be thoroughly understood. We do not think there will be any more mining "booms" in the State, nor are they at all desirable, as they do nothing but enrich speculators, who happen to be on the inside.

RIVER MINING.—Work is to be resumed mining the river at Big Bend this summer. Last week, A. K. Beaton, the superintendent, received a dispatch from Dr. E. V. Pierce of Buffalo, the president of the company, instructing him to go on with the work. Mr. Beaton informed an Oroville *Mercury* reporter that there are two places in the river he intends to mine. One is near the head of the tunnel and the other farther down. He will use steam power for his derricks and pumps at the first claim, and the water he flumes from this will make power for the claim below. Mr. Beaton does not believe the tunnel will carry the waters of the stream until about the middle of July, but he says they can get ready to mine inside of two weeks and continue three months. Probably 50 men will be worked from the start. Our people will be glad to hear of this. They believe that there is gold, and lots of it, in the river at Big Bend, and if any one knows how and where to find it, it is Andy Beaton. The *Mercury* also says: Things are booming at the Golden Gate and Golden Feather mines. About 300 men are at work in the mines, and many others with teams are hauling lumber and other material. For over two miles the river seems to be alive with men, and the great enterprise in all its departments moves on with the precision of well-regulated machinery. The great oval wall of the Golden Feather is crawling to the southern limit of the mine, and pretty soon the river will be turned from its ancient channel and the accumulation of centuries will be investigated.

CORROSION OF IRON AND STEEL.—The philosophy of the corrosion of iron and steel, the best way to avoid it and the best manner to remove it, is just now exciting much interest among both iron workers and iron producers. At a recent meeting of the Engineers' Club of Philadelphia, Mr. Radolph Hering read a paper on the corrosion of iron and steel, and referred to galvanic action as a principal cause. He gave the results of experiments on this subject, and principally of those made by Mr. Thomas Andrews of England. Wrought iron was placed in connection with numerous steels and cast iron, and exposed to sea water for about 300 days. From these it was found that metals corroded much faster when in galvanic connection than otherwise. The wrought iron (Wortley best scrap) resisted corrosion better than either steel or cast iron. The electro-chemical position of the steel changed frequently with reference to wrought iron, indicating that corrosion took place alternately in the wrought iron and steel. The position was almost constant, however, when connecting wrought and cast iron, indicating corrosion to take place almost entirely in the latter. Gravimetric results were also given, which showed the amount of corrosion in grains per square foot, per annum, under the conditions assumed in the experiments.

STERILIZING WATER.—Water is easily sterilized by keeping it at or near the boiling point for 15 minutes. Five minutes' heat is sufficient to destroy all harmful micro-organisms. Still less time suffices to destroy the disease-producing varieties which are recognized as liable to occur in water. Thus, merely raising to the boiling point a clear water containing the micro-organisms of malarial disorders, typhoid, cholera, diphtheria, or of enteric processes, and allowing it to gradually cool, ensures the destruction of these germs. They are also destroyed by keeping the water for from a quarter of an hour to half an hour at a temperature of 170° Fahr. Occasionally, however, very resistant but harmless bacteria may get into water. The brief heating renders them safe for drinking purposes, but when it is desired to destroy every micro-organism that may be present in a contaminated water, it should be heated for one hour and allowed to cool slowly. It may then be used for cleansing wounds or for alkaloidal solutions, which will keep indefinitely if no germs be introduced after the solution has been heated.

GOLD DISCOVERY.—William Pryde arrived in Winnemucca yesterday and reports that there is great excitement at Willow Creek over the discovery of gold near L. L. Rickard's (Montana's) ranch, this side of Disaster Peak, in the northwestern part of the county, near the Oregon line. E. M. Samples arrived at the camp Friday with a sack full of rock which he had taken from the ledge near the ranch. The quartz was pounded up in a mortar and found to be fairly lousy with gold. Samples came in for tools and immediately returned to commence work on the claims which he had located. Gold has been found in this locality before, but all efforts to discover the ledge were futile. All the miners at Willow Creek have left for the scene of the discovery. *Silver State*, May 13.

SANDALWOOD IN LOUISIANA.—It is said that a grove of the finest quality of sandalwood, 300 acres in extent, has been discovered in Louisiana. The trees are of immense value, and a company is to be organized to prevent them from becoming extirpated.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SOLD BY THE SHERIFF.—Amador *Ledger*, May 16: Last Monday the sheriff sold under judgment of foreclosure the Amador Queen mines, Nos. 1 and 2, together with 25-stamp mill and millsite. The property is situated in Hunt's gulch, Jackson district, close to the 40-stamp mill belonging to the Amador gold mine. A. S. Cochran & Co., of London, England, who is the principal owner in the Amador gold mine, was the judgment creditor, having purchased the claim from the original mortgagees and leinholders. Mr. Eisner of the law firm of Lindsey & Eisner of S. F., the attorneys for the Amador gold mine, was present at the sale; also J. E. Dye, the financial agent of the corporation in this county. The entire property was bid in by Mr. Dye for A. S. Cochran & Co., for the sum of \$11,150, which is some \$700 short of the judgment and costs. The owners have six months in which to redeem.

BUNKER HILL.—The Bunker Hill reduction works have been idle for the past week, as they are being cleaned up and undergoing repair. The mortars at the mill are also being fitted up, with the intention of starting up 40 stamps.

PLYMOUTH.—The Bay State Mining Co.'s shareholders convened in Randolph's hall on the evening of the ninth, as per notice, and effected a temporary organization by the election of a board of directors to serve for three months. The following are the names of the directors and their places of residence: W. T. Jones, Plymouth; K. F. Crocker, Drytown; W. A. Green, Plymouth; T. Price, S. F.; Mr. Young, Placerville; J. F. Parks, Jackson; A. J. Crain, Plymouth. A. J. Costa was chosen as secretary, and L. G. Norris, treasurer. Mr. Randolph presided at the meeting with marked ability; his experience in organizing the Drytown Consolidated standing him in good hand. The general feeling over this way is that the Bay State will start up one of the best mining properties in the State.

ATTACHING A MINE.—Amador *Dispatch*, May 16: The Bunker Hill mine near Amador City has been attached by John Mitchell, to whom has been assigned the accounts of the employees of that mine, for the sum of \$9934.75. The cause leading to this action on the part of the miners, we understand, is the reported failure of a bank in Philadelphia to which the mine belongs. Messrs. Caminetti & McGee are the attorneys for the miners. We understand that other suits are also being commenced for further sums by other parties who have employed D. B. Spagnoli as attorney.

Butte.

FROM OROVILLE.—*Mercury*, May 15: Alvinza Hayward arrived in Oroville last night. He and Messrs. Belding and Vail went to Forestown today, where they will join C. J. Nickerson and arrange to open the Shakespeare mine. The advent of Mr. Hayward in the Butte county quartz mines is significant. He is recognized as one of the most expert quartz miners on the coast and is a man of experience and wealth. We hope soon to chronicle good news from the Shakespeare.

Calaveras.

GOOD PROSPECTS IN CALAVERAS CO.—*Prospect*, May 16: Rumor has mapped out a large program of work for the coming months and if a fair percentage is inaugurated, ours will become a stirring section. First it is said that the great Union Water ditch will be enlarged so as to convey a vast amount of water, more than ever before, and that several hundred men will be required to push the work through this summer. Then in addition to this, it is supposed that the Vallecito Gold Mining Co. will begin the construction of their ditch to take its water from the Stanislaus river, and run thence to Vallecito where it will be judiciously handled in working the rich gold deposits of that place. Again the opinion is that the dam at Silver Valley above Blood's will require a large force of men in its construction this summer. This will be another great feature in the water facilities that are becoming perfected in this end of Calaveras. Before many years it can be strenuously argued that water is taking the lead here, and whiskey for once will have resigned itself to second place. Mining matters are looking up in this district; Condit & Co. have gone to Stanislaus to resume work upon the Pierce mine. C. Campbell is having a quantity of ore crushed from the Woods mine at Indian creek at his mill here and from all evidence the rock is going to run up to a high figure per ton. This crushing will be a test and it is presumed it satisfactory will mean more permanent and active mining operations on that piece of property. Buckminster's gravel mine at Douglas is steady in operations with a night shift and a day shift and tons of gravel are daily going through the flumes. The Norfolk mill and mine are constantly going on in regularity of labor, and though the yield is not publicly known, supposition is that the mine is above the average.

El Dorado.

PLACER MINING.—El Dorado *Republican*, May 14: C. A. Swisher and W. W. Stone have struck a good claim in Long Canyon, above Blair's sawmill. Lou Gignac and another man are at work ground sluicing in the claim and are finding some rich dirt. Lou was in town Tuesday and exhibited the result of three pans which aggregated about \$8 of rather coarse, bright, channel gold, one piece weighing over a dollar.

Nevada.

MINING INCORPORATION.—Grass Valley *Union*, May 13: The Gaston Ridge M. & M. Co. of San Francisco, to operate near Graniteville, in Nevada county, has filed articles of incorporation in the Secretary of State's office. The capital stock is \$1,000,000 and the directors Patrick Foley, Michael Bohannan, F. M. Cartan, T. F. McCarthy and J. F. Nugent.

OMAHA MINE.—The strong flow of water in the No. 10 drift, north of the Omaha mine, which was so troublesome several weeks ago, has greatly reduced in volume and the work of sinking the main incline shaft, which was interrupted, has been resumed.

THE MANZANITA.—*Transcript*, May 13: The local company recently organized to proceed with

the developments of the Manzanita drift mine at this city will begin the present week to grade for the hoisting and pumping works [that are to be constructed. The machinery will be operated by water from the company's own ditch. There is to be an incline on a grade of two feet in twelve, and having a perpendicular depth of 42 feet, which will reach the level of the channel. There will be a double track and an endless cable which will hoist the loaded cars and lower the empty ones. All the arrangements will be made with a view to cheap and rapid operation.

TAKING OUT MONEY.—Grass Valley *Union*, May 15: The miners of Cherokee, Butte county, are represented to be taking out \$3000 a month in a small way, by means of rockers and sluices.

HERMOSA MINE.—Preparations are nearly complete for resuming work in the Hermosa mine, and it only needs the putting in of a new sweep rod and the placing of a pump column to commence the pumping out of the shaft. The shaft is 180 feet in depth and there are only 80 feet of drifts to drain so the relieving of the shaft from water will be the work of but a few days. The mine has been idle since it was drowned out by water, winter before last, but heavier machinery has been put in the works and there will be no difficulty in handling the water in the future. The mine is not a wet one and the 8-inch pump that is being put in will handle the water easily. There is a two-foot ledge in the bottom of the shaft that looks well and is expected to give good mill results. The Hermosa location is 400 feet in length, extending from a point west of Watt Park to the head of Scadden Flat. The number of shares in the company is 30,000, all of which have been disposed of. The mine is regarded as a good prospect.

WHITE PINE MOUNTAIN.—Grass Valley *Union*, May 14: The mines of White Pine mountain have about 600 tons of lead ores for shipment to Salt Lake. The ores of White Pine are heavier in lead than those of any other section in the West.

DIVIDEND NO. 3.—*Foothill Tidings*, May 15: Dividend No. 3 of five cents a share, aggregating \$1500, was declared by the directors of the W. Y. O. D. mining company Saturday evening. The company has paid for the 10-stamp mill purchased recently and has a substantial treasury at its command, dividend No. 3 notwithstanding. The new mill is in course of erection, and with other improvements will cost \$15,000. Of these improvements a new boiler and engine, now in place, are not the least, as the hoisting and pumping plant as at present existing is of such capacity as to enable operations to a depth of 1600 feet. The shaft is now 800 feet in depth, and there is enough ore in sight to keep the new mill busy for a year. Of course, the increased milling facilities will permit the payment of larger dividends. Returns from a number of tons of sulphurets sent to the Selby Smelting Works by the W. Y. O. D. company are very gratifying, the gross yield being \$300 per ton and the net returns \$250 per ton.

NEW EUREKA TEST CRUSHING.—The New Eureka mine company's lease of the Crown Point mill has expired and the stamps are now at work on quartz from Williams & Co.'s claim on Slate creek. The test of the New Eureka ore, we are unofficially informed, revealed that it is of a low but nevertheless profitable grade, coming as it does from a large ledge and being cheaply extracted. The sulphurets, which are known to be high-grade, were not saved because of an accident to the concentrators.

STOCKHOLDERS MEETING.—The annual meeting of the stockholders of the Maryland Gold Mining Company was held Monday evening and the old Board of Directors and officers re-elected. These are: Wm. Young (of San Francisco), Rufus Shoemaker, S. P. Dorsey (Pres. and Supt.), C. H. Mitchell and Louis V. Dorsey (Sec'y and Treas.). No other business was transacted. Mr. Young, who is a former townsman, was present. He returned to San Francisco to-day.

Sierra.

VARIOUS ITEMS.—*Mt. Messenger*, May 16: Work at the Thistle shaft, near Gibsonville, is progressing satisfactorily, under the direction of F. A. Gourley. The tunnel is now 300 feet from the bottom of the shaft, across the channel. The bedrock pitched away from them before they got very far from the shaft, showing that the bottom of the channel had not been reached. The tunnel is all in gravel, and will be continued until the rim is reached, when a shaft will be sunk in the center. When once the lowest point has been found, work on the tunnel will be begun. We are informed that all the works will be in Sierra county. From a few loads of gravel the extension cleaned up \$70 last week. One piece was worth \$25. The Wide Awake Co.'s main tunnel was half in gravel the first of this week. Mr. Snap, a prospector, was in town the first of the week. J. Moulton and James McGregor expect to prospect their quartz ledge near Chip's Flat next week. Fred Morris, of the Tecumseh quartz mine, Logansville, is expected up in a few days with his family, to begin work on the mine. The snow is disappearing very fast. The Quincy stage goes clear through to La Porte now, with a sleigh, and Gus Berg, the driver, says if the weather continues to be pleasant that within 10 days he will be able to come from La Porte to Gibsonville with a wagon.

Trinity.

STRUCK IT.—*Journal*, May 16: W. F. Arnold was in from East Fork Wednesday and informs us that he struck the ledge the day before in the Thanksgiving mine, owned by Mr. Henry Junkans of this place. The ledge is from 18 to 20 inches in width, looks first rate and prospects very well. Reports from all parts of the county represent the business of mining, both quartz and placer, as being in an active and prosperous condition. The hydraulic miners have plenty of water and as they are making the best use of it, the season will prove with them an unusually good one.

Tuolumne.

ANOTHER STRIKE.—*Tuolumne Independent*, May 16: Last week a strike was made in one of the Pedro pocket claims on Brown's Flat, and worked by Messrs. E. J. Richards and Chas. Rudoff. About \$200 was taken out. We learn that Mr. James Stone and partner have been getting flattering prospects in their mine on Brown's Flat recently, with every indication of a good pocket in the near future. We hope it will prove true and that the gentlemen will reap a golden harvest that will make their hearts light and their pockets heavy.

NOTES FROM GROVELAND.—Sonora *Democrat*,

May 16: J. Quimby is busy at Sequoia crushing quartz from his mine, in an arrastra mill. The rock goes from \$25 to \$100 per ton. Santa Maria may prove quite a prosperous camp again if this mine keeps up its licks. Work of exploration is to be commenced this week on a very promising vein near John Smith's on the Yosemite road.

NEVADA

Washoe District.

THE WEEK'S DOINGS.—*Enterprise*, May 16: It is reported that a body of ore has been struck on the 1405 level of Ophir at a point about 90 feet north of the Con. Cal. & Va. line. If this strike of ore should prove to be the northern continuation of the ore development of Con. Cal. & Va. on the 1500 level, northeast of Con. Cal. & Va. shaft its importance would be difficult to estimate, but it would account in a measure for the recent rally in prices of stocks. With reference to the rumored strike in Ophir, Supt. D. B. Lyman last evening explained to an *Enterprise* reporter that on the 1405 level of Ophir toward the south end of the mine he was exploring a splendid body of quartz—at least 100 feet thick—and that he was cutting stringers of fair-grade ore occasionally. There is some hope entertained that it will make into a good ore body yet. The Alpha hoisting works are again in operation. The Washoe mill, of ten stamps, has started up on Justice ore. The Alta mill is now running five stamps, which will soon probably be increased to the full capacity of the mill—15 stamps. It was stated on the street yesterday, explanatory of the recent break in Con. Cal. & Va., that a clay slip had been encountered in the south drift on the 1100 level, but that the drift had passed through it and again penetrated the same kind of ore. This was given on account of the sudden break and equally sudden recuperation of the stock. Such a clay slip, running through a strong body of ore, would be an exceedingly strange occurrence, and the *Enterprise* does not believe a word of it. The slip, if it existed anywhere, ran across Pine street in San Francisco, and it was never visible at this end of the line. The heavy inflow of water in the Crown Point incline above the 1700 level has been conquered, the submerged Dow pump has been retrieved, and the work of draining the Gold Hill mines is again going on as usual. The following information has been gathered from the weekly letters of the superintendents:

ALTA.—The mill is now working five stamps on ore extracted from stopes throughout the mine.

YELLOW JACKET.—Are doing the usual amount of prospecting work, and preparing to open out on the 1200 to the 1300 level, preparatory to the extraction of gold bearing rock to be crushed at the Santiago mill.

CROWN POINT.—The north drift from the 300 stope, 11th level, is now out a total distance of 33 feet. It has passed through and the face is still in low-grade quartz. The 1000 level east crosscut from the main south drift is out a total distance of 78 feet, having been extended 21 feet during the week; the face is in porphyry, with streaks of low-grade quartz through it.

Justice, Kentuck, Con Imperial, Challenge, and Belcher are doing the usual amount of exploratory work.

SEG. BELCHER.—On the 600 level the west crosscut from the south lateral drift has been advanced 12 feet since last report, and is now out a total distance of 38 feet; the face is in a mixture of porphyry and clay. A portion of the week has been occupied in timbering the main drift.

SAVAGE.—We have hoisted 552 cars of ore from the 500, 750, 800, 900, 950 and 1000 levels. Shipped to the Mexican mill 557 tons and milled 669 tons; average battery assay, \$17.20. We have bulion on hand amounting to \$10,072.41. We have repaired and retimbered the E-street tunnel a distance of 500 feet. On the 800 level the winze started 80 feet north from our south boundary is down 24 feet in ore. At this point we have commenced stoping; it shows a width of 16 feet of fair-grade ore. On the 950 level the upraise near our south boundary is advanced 32 feet, top is in porphyry and stringers of ore. On the 1100 level the east crosscut from face of north drift was advanced 45 feet to the east clay wall. Opposite this we have started a crosscut west, which is advanced to feet in quartz giving low assays. From the east intermediate drift below the 1300 level the winze has been carried down the 85 feet and connected with the north drift on the 1400 level. The north drift, 1400 level, was advanced 23 feet; about half the face of this drift is in ore of good quality.

HALE & NORCROSS.—The winze from No. 3 east crosscut, 1400 level, is down 80 feet; the bottom is in quartz. No. 5 joint east crosscut on the south boundary has been extended a total distance of 105 feet to the east boundary of the vein. The main incline is now repaired 195 feet below the 1400 level, and have started to open the 1500.

SILVER HILL.—Southwest drift, 50-foot level, is out from shaft 20 feet; face in hard porphyry and clay. South crosscut, 160 level, is out from winze 520 feet; face in hard porphyry.

ALPHA AND EXCHEQUER.—Have completed repairs to shaft and resumed work in the mine.

SIERRA NEVADA.—630 level: West crosscut No. 1 from the northwest drift, 571 feet from the shaft, has been advanced 36 feet; total length, 382 feet. The formation is somewhat softer.

NEW YORK.—North lateral drift, 600 level, is out north of shaft 198 feet; face in porphyry. North lateral drift 1100 level, is out north of shaft 481 feet; face in quartz yielding low assays.

CHOLLAR.—The south drift, 1400 level, from the north 1st, is out 100 feet; face in porphyry. We are cutting out a winze station in the joint east crosscut on the north line, 1400 level. Extracted and sent to the mill the past week 545 tons of ore of the value of \$19.94 a ton, as per battery samples.

POTOSI.—The winze is down 4 feet below the 1400 level; the bottom is in porphyry and streaks of quartz. The south lateral drift from the winze station, 1300 level, is out 204 feet; face in quartz and porphyry. South lateral drift from the Chollar incline, 1100 level, is out 154 feet; face in clay and porphyry.

WARD COMBINATION SHAFT.—The only work done the past week has been confined to repairs to the 1800 level station.

UNION SHAFT.—West drift from the shaft, 900 level, is out 150 feet, making 46 feet during the week; the face is in hard porphyry.

OCCIDENTAL.—Extracting fair-grade ore from the 350, 400 and 450 levels. North drift from No. 1 upraise, 500 level, is in 92 feet; face in low-grade quartz. South drift from the same point is in 79 feet; face in low-grade ore. South drift from No. 1 winze, 600 level, is in 105 feet, face showing ore of average value—\$22 a ton. North drift from No. 2 winze, 550 level, is in 342 feet; face in low-grade quartz. South drift from No. 1 winze, 750 level, is in 81 feet; face in low-grade quartz.

UTAH.—Incline winze has been sunk 18 feet; total depth, 40 feet; the bottom of the winze is showing porphyry, clay and quartz, assaying low in the precious metals.

ANDES.—On the 420 level, east crosscut from south drift has been advanced 20 feet during the past week; formation, vein porphyry. East crosscut from the north drift on the 420 level was timbered and advanced 15 feet; face in quartz.

Candelaria District.

A DEEP MINE.—*Silver State*, May 15: The Holmes Mining Co. is now extracting ore from the 2100 foot level of the Northern Belle mine at Candelaria and obtaining a rare kind of silver ore that is pure turquoise in color and quite rich. The mine at that depth continues, as it has from the surface, to be as dry as a powder horn, and there has never been a drop of water encountered in it.

Tuscarora District.

NEVADA QUEEN.—*Times-Review*, May 15: South drift from east crosscut on 4th level Commonwealth extended 20 feet in vein matter.

NAVAYO.—The stopes above the 350-foot level continue to produce their usual quantity of ore. The water is not so strong.

DEL MONTE.—West crosscut, 3d level, advanced seven feet. Cutting out for chute and putting in timbers interfered with progress in the crosscut. Joint raise has been put up 20 feet.

BELLE ISLE.—The prospecting winze from the intermediate crosscut from No. 1 chute, 350-foot level, extended 5 feet; total 20 feet. The rich ore is getting wider.

COMMONWEALTH.—First level: Have retimbered on north side of shaft and extracted 18 cars of first-class ore, assay, \$203 per ton; also 39 cars of ore, average assay \$42 per ton. Fourth level: North drift has been advanced 20 feet and timbered. The whole face of drift in low-grade ore and shows a marked improvement as the drift is advanced. East crosscut extended 20 feet.

NORTH BELLE ISLE.—South drift from east crosscut, 400-foot level, extended 20 feet, the face still showing good ore. The stopes started over this drift are looking very well. Broke five cars of first-class and 81 cars of second-class ore. The stopes from the intermediate from No. 4 chute, 600 level, are looking about the same.

NORTH COMMONWEALTH.—First level: The stopes show more ore, getting wider but not so high grade. There have been crushed at Union mill 270 tons of ore; assay from battery pulp, \$27.60 per ton. Crude hullion on hand, \$23,000. Concentrating plant started Monday. Crushed 200 tons of ore, average assay, \$27 per ton.

ARIZONA.

THE BLACK BEAR.—*Silver Belt*, May 9: Mr. O. B. Hardy, owner of the Black Bear mine located in the Coeur d'Alene Idaho, has closed a deal with Mr. W. McCaskey, of the Edison General Illuminating & Power Co. of New York for the construction of ten electric drills, which will take the place of compressed air drills in his mine. The amount expended for this purpose has been about \$8,000. "The company," said Mr. Hardy, "goes at it in such a manner that I have extreme confidence in the value of the machinery. They ship all the machinery, pay all the expenses and run the drills 40 days before I turn over a cent. The Yavapai Mining and Storage Co. is doing a good business in their placer claims at Camp Hattersley and French creek. At Hattersley a hydraulic apparatus is in successful operation, and a large quantity of gold is being taken out daily. The company work 50 men at both camps and thus far the claims have proven very satisfactory. Hydraulic works will soon be in operation at French creek, when the results will be much more satisfactory.

BLOWN UP.—*Tomahstone Prospector*, May 12: Jake Bowman came over from Bisbee this morning and brings the report of an accident in the Copper Queen mine last night in which John Torpey and W. Nelson were horribly mangled by a blast. It seems that they had put in five holes and lit the fuse of all but one which kept them longer than anticipated but they thought of no danger until the first hole went off and blew them headlong into the drift. One of their companions happened to be near by and procured assistance and took them to the surface, where willing hands conveyed their bleeding bodies to the hospital. Faint hopes are entertained of their recovery.

NOTES.—*Prescott Courier*, May 13: Miners of Big Bug district tell us that Superintendent Clark is having good substantial work done in the Silver Belt mine. His Honor, Mayor Howard has a force of men working in a Groom Creek district mine. Twenty thousand pounds of very high-grade silver ore were recently shipped to El Paso by Tip Top district miners. Superintendent Murphy has gone to Congress to start the mill. United Verde is shipping carloads of copper-silver hullion. Mr. Lawler, of the Hillside mine, has teams on the road, hauling very rich silver ore. Work is progressing favorably in Phelps, Dodge & Co.'s camps—Copper Basin, Senator and Big Bug.

MINING NOTES.—*Courier*, May 21: Miners of Big Bug district tell us that Supt. Clark is having good substantial work done in the Silver Belt mine. Mayor Howard has a force of men working in the Groom Creek district mine. Twenty thousand lbs. of high-grade silver ore were recently shipped to El Paso by Tip Top district miners. Supt. Murphy has gone to Congress to start the mill. United Verde is shipping carloads of copper-silver hullion. Mr. Lawler, of the Hillside mine, has teams on the road, hauling very rich silver ore. Work is progressing very favorably in Phelps, Dodge & Co.'s camps, Copper Basin, Senator and Big Bug.

BRITISH COLUMBIA.

HOT SPRINGS.—*Nelson Miner*, May 16: On Tuesday there arrived at Nelson on their way to Ainsworth, a party of Montana men who are largely

interested in Hot Springs district. The members of the party were A. W. McCune, F. E. Sargent, William Thornton and Scott McDonald. They were met at Nelson by Henry Giegerich and A. D. Wheeler. Mr. McCune, as a partner with Messrs. Giegerich and Wheeler, has been interested in the district since its discovery. Mr. Sargent is secretary of the Anaconda Co., and comes in along with Mr. Thornton, who is cashier of the first National bank of Anaconda, to talk over the interests recently sold by A. D. Wheeler to W. L. Hoge. Mr. McDonald is a mine manager in the Cœur d'Alene country. Mr. Hoge, who purchased Mr. Wheeler's interest in the Skyline, Krao, Crow Fledgling, Blackbird, Maestro, Banker, Pataha, Attended, Bugaboo, Libby, and two or three side locations, is president of the First National Bank of Anaconda, and is associated in business with Marcus Daly, manager of the great Anaconda mines and smelting works. The mere fact that he has secured interests in Hot Springs district, should give claim owners confidence, for he is not a man likely to purchase worthless mining properties. As soon as a boiler of larger capacity can be got to the ground, the work of sinking will be resumed on the Skyline. Work will also be commenced on the Krao.

ANOTHER GOLD MILL.—The new trail to the Whitewater mine on Rover creek will be finished on Tuesday. The mill on the Gold King has been taken down, and will be packed to the Whitewater ground next week. A triumph vanner was received at Sproat on Monday. Work will commence on the mill building on Tuesday, and manager Davys expects to have the mill running the first week in June.

COLORADO.

LITTLE ANNIE.—*Aspen Times*, May 12: Last fall the Little Annie Mining Company at great expense, aided a little by a few business men of Aspen, built a good wagon-road from the Castle creek road to Richmond hill. This road is open for the free use of all who desire to travel it. Now that the snow is off, the county should put its main road in repair and declare the Little Annie road a county road and repair it. The county will be ready and certain to receive its taxes on ore output and improvements of that section, and it would be no more than justice to tax-payers if a little money was appropriated by the county commissioners in this direction. A cave was struck in the north drift of the second level of the Little Annie mine last evening which seems to be a pot of mineral. It will be explored to-day. The company is now advertising for bids to haul the output of the mine to Aspen. Regular shipments to begin on the 20th. The entire ore body pays to ship without sorting. Three grades of ore will be made hereafter. The third grade will be stored at the mine for future treatment by low-grade processes. The mine is proving up more ore every day, and the big ore body found in the north first level is now being reached as is evidenced by the cave encountered yesterday. Parties who bought stock at 15, 20, 25 and 30 cents, and are trying to sell it at 27, will soon learn that the Annie is one of the best investments on the boards in Aspen.

THE PONTIAC.—A great change occurred yesterday in the drift running south in the Pontiac and Manager Brown thinks he will be able to announce a strike in a short time. The work will begin from the Iowa shaft in a day or so.

SAN JUAN.—*Aspen Times*, May 20: The prospects for an active mining season in San Juan Co. this year are all that could be desired. Notwithstanding the heavy snowfall in the latter part of the winter there is no more snow in the mountains than is usual at this time of the year, and that is going fast, as is evidenced by the booming creeks and rivers. Trails are being opened to the mines, and pack trains are beginning to come in from their winter ranges. The mines under development during the snow months all show the immense benefit that has been derived, and great reserves of rich ores have been opened up, which will in a few weeks be sending forth a silver stream that will permeate the business marts of our city and make our gulches teem with busy life.

NOLAN'S CAMP.—The latest from Nolan's camp is to the effect that 25 men are steadily employed in building a good road from the camp to Agüla, the station on the Denver & Rio Grande road, and a mill is getting into shape to go in there at once. On the mines a great deal of development work is going forward, and on all sides the indications are that a good paying camp will be the result of all this work.

IOWA GULCH MINES.—As a result of a great amount of development, the portion of Iowa gulch mining section running along the lower slope of Long and Derry hills, on the north, a considerable amount of ore was found there last season, but the chances are that this season's work will, however, discount last year's, and that at least two if not four mines will be added to our list. Among the best developed during 1890 at that point was the Frank, in which, at a comparatively shallow depth, some fine lead ore was found, and the data furnished by that work induced the owners of contiguous properties to start up. The strike or trend of the ore chute, being known, a shaft on the C. M. was sunk, in which some good ore was found, though it was thought that the workings were not deep enough, and the shaft is now being carried down.

DAKOTA.

ANOTHER PROCESS.—*Deadwood Pioneer*, May 19: The Colorado Gold & Silver Extraction Co. of this city, which uses the McArthur-Forrest, or cyanide process started its trial or test mill the past week. The process consists in crushing the ore so it will pass through a 40-mesh screen, when the ore is treated raw with a 1 per cent solution of cyanide of potassium, which is expected to dissolve the gold and silver, which is precipitated from the solution on metallic zinc. The new mill has ten stamps, 900 lbs weight which drop six inches 100 times per minute. The usual system of using different sized screens, passing the coarse ore back to the stamps for second crushing is used. All the ore before passing to the tanks will pass through a 40-mesh screen, but what portion of it will pass through finer screens is not known. The crushing of course is dry. From the stamps it is conveyed to cars where it is weighed and charged into the agitators, which are wooden revolving barrels 4½x8 feet. The charge for each barrel is 2½ tons of ore and 1½

tons of water, 1 per cent of which is cyanide of potassium. Both ore and water are accurately weighed. The interior of the barrel has longitudinal flanges which assist in mixing the pulp and water. The barrels are kept revolving for from six to ten hours, when the gold and silver are expected to be in solution. From the barrel the charge is dropped into circular tanks containing a false bottom four or five inches above the true bottom. The false bottom is covered with canvas, through which the liquid is filtered. The filtering is done from below by exhaust suction. The liquor is then pumped into vats from which it is slowly allowed to pass through zinc shavings, on which the gold and silver are precipitated. The liquor is then somewhat weakened and is restored to its 1 per cent cyanide strength, when it is ready for use again. Once washing the pulp is said to remove the last trace of cyanogen with its gold contents. The mill is fitted with two agitators and all needed tanks, and has a capacity of 10 to 12 tons per day. The consumption of cyanide is from two to three pounds per ton of ore treated. In a mill of 20 tons daily capacity, with wood at \$5 per cord and labor at \$2.50 to \$3 per day, the cost of treating ore should not exceed \$5 per ton.

JIM CREEK MINES.—Development work is being done on a great many claims and recent discoveries are very encouraging. Considerable work is being done on the Alliance, and the owner, Dr. Terry, is well satisfied with his prospects, as he has found a ledge of galena and carbonate ore. This property is supposed to be on the same belt as the Caliboga, Silver Reef and Jupiter lodes. On the Honduras some work has been done, and the outlook is good, as the same character of ore is found as on the Caliboga and others. This property is owned by Jack Wilson and Jack Forsythe. Jack McLaughlin arrived from the camp in Prosperity gulch, where himself and F. Thompson have been prospecting, and he exhibited some fine specimens taken from the Extension lode, an extension of the Alliance.

A FALSE REPORT.—The Sioux City Journal says that a letter received to-day from W. N. Nason, secretary of the Omaha Board of Trade, denies in toto the story started by the *Chicago Tribune* that the two committees sent out by the Omaha Board of Trade last year reported unfavorably on the Black Hills tin mines. Instead they made very favorable reports in writing and the matter will be brought up at the next meeting of the directors of the Board. Mr. Nason says it is incomprehensible to him how the story that the committee reported unfavorably was started.

IDAHO.

STORMY HILL.—*Idaho Avalanche*, May 9: On the Stormy Hill mine drifts are now being run both north and south at 260 feet from the surface. Only a few men have room to work at present, consequently the amount of ore taken out is not large. As soon as room is made, stops will be started. The ore taken out, it is thought, will mill about \$40 per ton. Some very rare and beautiful crystals are now being taken out of the lower drift in the Trade-Dollar mine. They are streaks of mica from one to three inches long, half an inch or more in diameter, a beautiful emerald green in color, and translucent. They are attached to quartz crystals found in crevices in the ledge. We have not found any miner who had ever seen similar mica formation elsewhere. A rich strike has been made a mile north of Spring City, Nev. This is a lode that parties have been trying to find for quite a number of years, as rich float has been found on several occasions upon the hillside by different parties. The Silver State is of the opinion that this find will be apt to create another boom for Spring City, and will be an encouragement for the new company that has but recently come into possession of the Paradise mines to push their reduction works to completion.

LOWER CALIFORNIA.

MINERALS IN SONORA.—*Lower Californian*, May 14: U. S. Consul Willard of Guaymas reports to his Government as follows, regarding mining matters in Sonora: The quantity of mineral ores exported during the past year from this consular district is more or less the same as the preceding one. Those from the north and central part were sent to the reduction works in the United States; those from the south (Alamos) go generally to the port of Mazatlan, Sinaloa, and are there reshipped to Europe or the United States by vessels. The concession granted by the State Government to certain American citizens to erect smelting and reduction works has not been complied with, and Sonora to-day has no smelting and reduction works where gold and silver ores are purchased and reduced, or where small mine-owners can have their ores treated. The only class of mines worked are those of silver and gold, but principally the former. Veins of copper, lead, iron, antimony, and deposits of cinnabar and coal are found in different parts of the district, but are not developed. The coal deposits have been worked to a small extent to supply fuel for the steam works of the mining companies in the immediate neighborhood. This coal, anthracite, is said to be abundant and of good quality, containing from 80 to 90 per cent carbon. The veins or seams vary in thickness from 4 to 10 feet. These deposits can be reached from the coast over easy grades.

MONTANA.

NOTES.—*Inter-Mountain*, May 11: The suggestion of the *Miner* that the city government provide for the employment of as many men as possible by beginning the work of paving the streets, is a most excellent one. The cost to the tax-payers will be no greater now than later, while the benefit to the labor and business interests would be far-reaching and immediate. There are 1500 idle miners here while the Anaconda is closed down. They are good citizens, most of them are married men and all of them are highly skilled. The camp cannot afford to lose them and they will remain here if temporary occupation can be provided for them. The mining estates and territories should be on the alert touching the question of Mexican lead ores. While western representatives and senators are resting in fancied security the owners of Mexican lead mines are exerting themselves to the utmost to evade the provisions of the lead clause in the McKinley bill and on some technical grounds have actually procured a

partial suspension of the regulation affecting lead in silver ores. Congressman Dixon is no doubt personally opposed to a tariff on lead or anything else, yet it is hoped that on behalf of our lead mine owners he will bestir himself in the matter and at least lay before the authorities the statements of the Montana lead ore producers.

TOSTEN SMELTERS.—*Mining Journal*, May 13: The smelter at Tosten, which has been closed some time, will be fired next week, arrangements having been made for a continuous supply of ore. The managers claim to have fully demonstrated the utility and practical success of their process; in this it is to be hoped that they are not deceived, as the treatment of ores under the process can be more economically accomplished than under any of the methods now in use.

NEW STRIKE.—*Mining Journal*, May 13: From a private letter, dated the 7th inst., the *Journal* has been privileged to make the following extracts: The excitement is pretty high here over the recent strike of native silver in the 500-foot level of the Cumberland. The company was making a raise up to the 305-foot level and struck on the footwall twin to four feet of very fine ore with native silver all through it. The smelter will start by the 18th or 20th inst. The Yellowstone is looking finely and good reports come from most of the properties being worked. There is considerable talk of a custom smelter being built at once. Castle's position as a great mining camp is assured beyond question, and it ought to be connected with Helena by a direct railroad.

TREASURE HILL MINING CO.—*Montana Mining Journal*, May 13: A description of this property recently appeared in the *Journal*. It consists of a group of four claims, the main lode having been opened along its length over 1800 feet, at every point disclosing the fissure carrying high-grade ore. Work is now progressing from the 100-foot level, which will be sunk an additional 50 feet, at which point levels will be run in each direction. No property in this camp gives a more favorable promise of becoming a great mine than does this. Crow creek is reached. Up its right bank Eureka and Eagle gulches lie, in both of which discoveries have been made and prospectors are busily engaged penetrating Nature's secrets. Beyond Crow Creek, Cedar Plain, Johnny's Gulch, Nigger Ridge, Ruby and other districts have been developed from which ore is being shipped. The districts covered have during the past winter been constant ore shippers, the ores from Indian creek going to Bedford, from Ben Kumber and Little Bonanza to Vose siding, and from the H. H. and East Pacific to Ryan siding. All this development has been accomplished in three years, and this season will witness more advancement than has been made altogether heretofore and the prediction is here made that by Dec. 1, 1891, the daily output will not be less than 100 tons. The credit of this work district is entirely due to the tireless prospector and men of small means, almost without exception Helena men, and to them shall be given the credit and to them will come the profit.

NEW MEXICO.

CARETA MINE.—*Southwest Sentinel*, May 12: J. Douglas Smith and J. W. Stone, owners of the Careta mine, at Bald mountain, have just received the returns from their last shipment of ore sent to El Paso; it ran 135.3 ounces in silver, 7 ounces in gold and 5 per cent in lead. The same owners have quite a quantity of ore sacked up on the Mayflower mine that will market about \$150 a ton, and a large quantity of low-grade ore that will run about \$40 to the ton, which they are holding over for the Flager mill to start up.

OREGON.

MINING ITEMS.—*Times*, May 15: T. P. Judson of Grant's Pass has bonded the Swacker quartz mine in Foots creek district and has put a mill on it, which is kept busy crushing ore. Considerable prospecting must be going on in southern Oregon, as a large number of location notices and mining guides are being purchased at the *Times* office. J. A. Harvey of Foots creek has discovered a well-defined quartz ledge which prospects very well. He crushed some of the ore and realized \$5 from a single pan. The extensive mines of Simmons, Cameron & Co., after several years of preliminary preparation, are now being operated on full time. A good season is expected there. The Sterling M. Co. has a good supply of water and two pipes at work. It is expected a good cleanup will be made at the end of the season, which is several months hence. The Wimer mines will probably be operated for several months this season, as the Circuit Court has dismissed the receiver, which action will probably allow Wadleigh and Co. to take possession again and work the property. Zach Cameron of Uniontown, who is interested in the Simmons-Cameron mine near Waldo, made them a visit this week.

UTAH.

DEEP CREEK.—*Park Record*, May 9: Boom, boom, and Deep creek grows deeper, the desert gulches narrower and water more abundant. If a concerted newspaper howl about Deep creek will build the new railroad and pull the Salt Lake real estate men out of the hole, something will have to be accomplished. If it fails, smash goes the inflated realty bubble, and mourning will be the order of the day in Zion. Something must be done, you know, or many will be buried.

A NEW DISTRICT.—*Park Record*, May 9: Mr. J. J. Daly was out from Salt Lake this week and during his stay in town made a brief visit to the *Record* office. From him it is learned that the Daly West group will be actively developed during the coming summer. A new and extensive hoisting plant will be erected and a fine working shaft put down. The Daly West ground lies between the old Daly group and the Anchor, and as the vein shows up strong at both ends of the property there can be but one result in developing it, and that is a big mine. The ground is owned by Mr. Daly and R. C. Chambers, both thorough mining men and possessed of ample means to prospect the property in a thorough manner. The group embraces some 3000 feet on the vein, and when opened up to working advantage will employ a force of some 200 men. Thus the resources of Park City are being gradually developed and her output steadily increased, and

little doubt is entertained but that the output of 1891 in Park City will be at least double that of any previous year. Mr. Daly says active work will commence as soon as the snow is off the ground and trouble from surface water ceases. The papers may do all the howling they wish concerning Deep Creek, Dugway and other districts, but when the grand total is figured up, it will be found that Park City is the king pin in the whole list, if she does not turn out more ore and bullion than all the balance put together.

WASHINGTON.

SKAGIT'S MINERAL WEALTH.—*Mining News*, May 16: During the last year no mining region has attracted so much attention as that portion of Skagit county lying at the head of Cascade river, on the dividing line between Skagit and Okanogan counties, not known as the Cascade mining district. The *News* is indebted to Geo. Rouse for the following summary of the work done, and the present outlook for the various mines: The Boston vein, now owned by a syndicate of Helena men, is nine feet wide, three feet of clean ore running 100 ounces to the ton, and six feet of concentrating ore. A tunnel has been run in for some distance on this vein. The Epoch is a small vein containing 16 ounces of clean ore and 20 ounces of lead ore. The Ontario is a 16-foot vein, undeveloped. The Queen Sabie, although a small vein, being only three feet in width, is very rich. A tunnel has been run in on this vein at a distance of 82 feet. The Doubtful is a 20-foot vein. On this lode a drift has been run in for distance of 55 feet. El Capitan is a ledge of 20 feet in width. The Galena shows an 18-foot vein, on which a drift has been run for a distance of eight feet. The Franklin is a five-foot ledge with three feet of good ore. On this vein a drift has been run for a distance of 12 feet. The Adolph is a six-foot ledge which has been tunneled for the distance of 12 feet. The Cascade, a monster of 20 feet in width, has been tunneled for a distance of 100 feet. The Kildare yields rock that assays 100 ounces to the ton and shows a superior grade of ore. In addition to these mentioned are numerous other ledges which have been located, but are entirely undeveloped. There is no mining section that is attracting so much attention at present as this new El Dorado, and the coming season will witness great development of these valuable mines. If this section proves as rich as the prospects warrant, there will be a large city built at some point on the upper river, probably in the vicinity of Sauk, or possibly a little farther up the river. The greatest need at present is a road over which supplies can be taken. At present it costs a small fortune to pack in the supplies that are absolutely needed. It is a matter of great importance to this county that the commissioners take some action looking to the opening of a wagon-road from the mouth of the Sauk to the mines. A liberal appropriation by the county for the opening of the Cascade road will be a judicious investment and will return a hundred fold of the outlay to the county.

COAL.—*Ellensburg Capital*, May 14: It is said that an effort will be made to save the big blocks of coal from the Roslyn mine, which were used in the arches at Tacoma on the occasion of the President's reception, for use at the World's fair. One of these blocks weighs 17,000 pounds and is the largest ever produced in this State. It is proposed to have the arches in the Washington exhibit made only of the productions of the State, and the blocks of coal may be utilized in this manner. This will be a good advertisement of our State and county at the grandest Exposition the world has ever known.

IRON.—Joshua Pierce made a report of a trip to Ellensburg and the Skagit valley in the interest of the iron industry. He was convinced that there were immense fields of iron in both these localities and that Tacoma could not do anything more profitable than to foster them. It did not make so much difference where, but either on the Sound or on the main line of the Northern Pacific would be directly tributary to Tacoma and, therefore, more beneficial. Mr. Pierce was very earnest about the matter and entreated several members of the Chamber of Commerce to talk. They were unanimous in thinking something should be done to develop this important interest.

ABOUT MINES AND MINERS.—*Okanogan Outlook*, May 8: J. W. McGregor, Ben Hedrick and Henry Doheny returned Wednesday from Palmer Mt., where they have been doing development work on the Yellowstone and Gladstone claims. Sieve Howland, who has the contract to sink a hundred feet on the Ivanhoe, was in Concoully Thursday after supplies. He reports that they are now down 30 feet and sinking at the rate of two feet per day. John and Rol Seibert are working on their gold properties on Palmer Mountain. They have located an extension to the Fairview lead, which has produced some of the handsomest free gold specimens ever found in the country. The boys have several good prospects in the district, any one of which is liable to make them rich. Gus Leiber left Wednesday morning with a wagon load of tools and provisions for the Lime Bluff district, where he will spend several months doing development work on the Eureka and Lulu claims, in both of which he is interested. Geo. Cooper returned Monday from a trip to Tacoma. Mr. Cooper was interested with T. L. Nixon in a number of mining claims in this district. He informs us that the death of Mr. Nixon will not interfere with the development of his properties here, as everything was bequeathed to his wife, who has signified her intention of carrying out her husband's plans and schemes as near as possible. She will spend several thousand dollars in developing her mining interests on Mineral hill. Development operations are now fairly under way at the Ivanhoe mine. A force of men are engaged in sinking a new shaft for the purpose of determining the dip of the vein, which at the surface lies almost horizontal, but gradually assumes an upright position as depth is gained. They are now at work with a plow and scraper, removing the soil and uncovering the vein. Mr. Cowherd estimates that the amount of ore which has been uncovered in this way exceeds 1000 tons. One man will be kept employed all summer sorting ore for shipment to the Tacoma smelter. George Forrester, superintendent of the Toughnut, informs us that Col. Wallace has returned from San Francisco and will be in shortly to commence work on the mine. The amount of development which the company proposes to do this season will give employment to about 20 men.

MECHANICAL PROGRESS

Improved Manufacture of Staybolts and Tubes.

A device has recently been patented for rolling hollow staybolts, and a company formed for their manufacture at Cuyahoga, Ohio. The process is described as follows: Two pieces of iron rolled in U-shaped section are laid together and wired in that position. These parts are then heated to a welding heat and run through rolls. As the welded tube comes from the rolls it passes over a mandrel, which fills the interior. Before reaching the second pair of rolls it cools slightly and shrinks upon the mandrel. In the second pair of rolls it is drawn from the mandrel and the interior cleared by slag and cinder. In this way, by five repeated operations, a hollow staybolt is obtained, which has a uniform interior diameter. The material, of course, must be of the very best quality of charcoal iron. The helts are made in lengths of about six feet. The advantages of hollow staybolts are well understood. A considerable saving in expense can be made by using hollow staybolt iron, instead of drilling the ends of the bolts after they are in position.

Compound Metallic Tubes.

Nearly allied to the above is a new process for the manufacture of compound metallic tubes, tubes of one metal, covered or lined, or both, with another metal, invented by Geo. H. Everson of Pittsburgh. To line a tube a hard mandrel is taken, the diameter of which is the same as desired for the inside of the lining of the tube when finished. The metal lining is then placed around the mandrel, and rolled through or between hard surfaced rolls, until the lining is reduced to the desired thickness. Then the tube that is to be used is slipped over the lining, and the rolling process continued until the tube is rolled tightly into the lining, and reduced to the outside diameter desired, after which the mandrel is removed and the tube cleaned. If it is desired to cover the tube as well as line it, the mandrel is put inside the lining, the metal cover is slipped over the tube, and the rolling process continued, until the metal cover is rolled down tightly upon the outside of the tube, and the thickness of the covering desired is obtained, after which the mandrel is removed, and the compound tube finished in the ordinary manner.

Labor-Saving Machinery.

Much has been said of late in regard to the influence of labor-saving machinery on the scope of labor, and it has been stontly held by many that the present condition and future prospects of mechanics in this country (England) are far less satisfactory than they were in our earlier history, before the great advance in the introduction of labor-saving machinery. But the most careful-thinking people, even among our best mechanics, hold to the contrary and refute the argument used by the grumblers who say that the mechanic is not so much in demand, and not so much respected, socially, as he once was. At the time when steamboats, railroads and labor-saving machines were beginning to be constructed, no doubt wages were good, and the services of the mechanic held in high value. Circumstances then were such that for a time an unusually lively impetus was given to that department of labor peculiar to his vocation. The field was wide and sparsely tilled, and with no great degree of effort yielded rich returns. But after all, the methods of the time, if enterprising and vigorous, were yet rude, and of a nature necessarily so transitory that they soon yielded before more disciplined efforts and more careful, exacting and intelligent requirements. So the hasty methods of the mechanics of former days, and the few rude appliances and tools they used, did good work in their time, but would not be suitable now. With the growth of the country, machinery has increased, and the mechanic has commensurably gained in intelligence. The result is natural enough, and desirable. Now we make more devices in a day than would have sufficed for a month 30 or 40 years ago, and modifications and improvements, one after another, crowd upon each other with astonishing rapidity. The mechanics of to-day are obliged to make themselves acquainted with the manner of operating multifarious contrivances, and in such connection must continually make practical application of many of the principles of natural philosophy, the laws regulating steam, etc. Who doubts that many more well-educated and intelligent men are found among the ranks of British craftsmen than formerly? If anything, the community awards the best and most worthy members of this class a higher social position than that possessed by their predecessors of a generation or more ago.—*Machinery, London.*

TWISTED NAILS.—The newest thing in nails is a twisted wire nail, which is a cross between a screw and an ordinary plain wire nail. The idea is of English origin, and it is supposed to represent as great an improvement upon the plain wire nail, as that useful invention is over the old iron nail. As is well known, the common iron nail tears and crushes the fibers of the wood as it is driven, and its tapering shape destroys the greater portion of its holding powers when it is partially withdrawn. The plain

wire nail being pointed and smooth, does not crush the wood fibers as the iron nail does, but presses them aside. As the diameter of the nail is the same throughout its length, it fits as tightly and holds as firmly when partially drawn as when driven home. The twisted wire nail not only crushes the fibers of the wood less than the other two forms of nail, but by its screw shape possesses a much greater holding power than either of the other forms. Quite similar to this screw modification of the wire nail is the recent American idea of making a wood screw that will drive nearly as well as a nail, and yet can be withdrawn by means of a screw-driver as readily as any screw.

Iron and Steel Ships Without Frames.

Patents have been granted in England for a new method of shipbuilding that will probably reduce the cost of punching and riveting from 80 to 90 per cent. Should the experimental ship now under construction on the Thames prove successful, lake shipbuilders will be interested as—per cent of the cost of steel steamers on the lakes is charged to punching and riveting, and if four-fifths of that could be retrenched by this new process, in addition to the cost of framing material, it would be worth consideration.

Industries, London, has the following to say of the invention: "Naval architects have for many years attempted to apply hydraulic riveting to the building of our ships, but hitherto they have only succeeded in applying it to a very limited part of the structure. A new method, which will admit of the complete application of hydraulic riveting, the invention of Mr. A. C. Holzappel, of 57 Fenchurch street, London, about to be introduced, consists of building a ship of holed plates, or plates flanged on all four sides. The invention was thoroughly studied by Mr. Holzappel in conjunction with several naval architects and engineers, and he has now so far progressed as to arrange for the building of a trial ship, a vessel of small size, to be built on the river Thames.

It will be seen that the adoption of this method dispenses entirely with the use of frames and keelsons, and that the flanges of the plates will form an ample substitute for these. For riveting together these flanges a movable hydraulic machine of very light structure can be used, and a similar machine will also be used for the punching of the rivet holes, both being simultaneously punched, and the rivet holes being in consequence perfectly fair. Countersinking and surface riveting is consequently entirely dispensed with, and the labor required for the punching and riveting will be reduced from 80 to 90 per cent on the present total for wages. A second patent for simultaneously shaping and flanging the plates, will also be acquired by the company, but the ultimate intention is, should the method under notice prove a practical success, to shape and flange the plates in heavy cast iron or cast steel dies by powerful hydraulic pressure, and to then build a large number of ships of the same sizes and models.

This experiment in a quite new departure in shipbuilding will no doubt be watched with much interest by shipbuilders everywhere. Should the expectations of the inventor be fully realized, this method will prove a very important advance step in the economy of iron shipbuilding.

CASTING IN BRONZE.—American foundries do not as yet seem to succeed with bronze castings of any great size. There is one foundry in New York which can do good work, but the statue of Columbus, on the Drake fountain in Chicago, will be cast in Florence. Prohasco, who is having the Grant statue done for Lincoln Park, will have to have his statue cast in parts, and one of the hind quarters had to be recast entirely. The art of casting big statues all in one piece had long been lost, but it has been rediscovered. The process is called *cera perdue*. The other method is the sand process, just like that used for stove castings, but the joints have to be filed smooth and then soldered. In that way the artist's touch is lost and the skin of the metal, the patina, is scratched and spoiled. The *cera perdue* is the wax process. First the clay model is made. Then a plaister reproduction of that is made. From that is taken a matrix. That is coated inside with wax as thick as it is desired to have the bronze, say a quarter of an inch. A core is put inside of that, which would be a mold of the inside of the statue when completed. There is a hole in the bottom of this matrix. It is put in a pit and heated until all the wax is melted and runs out. The melted bronze is poured in between the core and the matrix, and there's your bronze casting. It costs about \$1000 more than the sand process for each statue, but it is much preferable.—*Age of Steel.*

"**Pig Iron**" is a mere play upon the word sow. When iron is melted, it runs off into a channel called a sow, the lateral branches of which are called the pigs. Here the iron cools, and is called pig iron. Sow has nothing to do with swine, but is from the Saxon 'sawan,' to scatter.

AMERICAN HARDWARE FOR SIBERIA.—A large shipment of hatchets was recently made from this city, upon special order, for Siberia. That country is beginning to be a large buyer of agricultural implements, and it will continue to grow in importance from year to year.

SCIENTIFIC PROGRESS.

A New Solvent for Cellulose.

Hitherto we have had no acid solvent for cellulose but such as in dissolving it bring about marked changes in composition and properties. In dissolving, the cellulose is resolved, *e. g.*, by the action of sulphuric and phosphoric acids, into products of lower molecular weight and cannot be recovered from the solution. Concentrated hydrochloric acid, as is well known, attacks cellulose profoundly. When digested with the acid in the cold the fibers are completely disintegrated, and the resulting modification, obtained as a white powder, manifests very different properties from the original. When warmed with aqueous solutions of the alkalis it is colored deep yellow, and the products of hydrolysis are powerful reducing agents (aldehydes).

This observation is of importance, as it enables us to investigate some points in the constitution of cellulose for the determination of which such an acid solution is an essential condition. The solution of cellulose obtained by heating it with concentrated solutions of zinc chloride may also be diluted with hydrochloric acid, without precipitating the dissolved products, but the solution by the new reagent has the double advantage of being instantaneous and of being prepared, therefore, with the minimum of resolution of the cellulose into bodies of lower molecular weight which usually attends the somewhat prolonged heating necessary for complete solution in the aqueous solution of zinc chloride.

The reagent we also find of great value in the investigation of structural points, *i. e.*, as an acid to microscopic work in the province of the vegetable fibers. All forms of pure cellulose are rapidly dissolved by the reagent, and the various stages preceding their final disappearance may be observed under the microscope, the observation throwing much light on structural peculiarities. The raw fibers, *e. g.*, cotton and flax, are not dissolved, at least only partially, but swell up under the action of the reagent, with the result that the structural features are brought out with great prominence. Jute and the ligno-celluloses generally are dissolved by the reagent, and many of the adpol-celluloses also. We are investigating these actions more closely and hope shortly to publish an account of our observations. In the meanwhile we commend the reagent in question to all who are engaged in the chemical or microscopic investigation of the vegetable fibers.—*Chemical News.*

How Ice is Formed

A person who has never closely observed the operation of nature's great ice factory will be surprised to find how interesting it is. You need not go outside of a comfortably heated room to do this. Just place a pan of water on the window sill, when the temperature is below the freezing point, and you will soon see something that cannot fail to interest you. If you happen to have a magnifying glass, a single lens, so much the better, for the magnifying power will reveal much of the delicate work of ice making that is invisible to the naked eye.

Anyway, as you closely watch the surface of the water you will soon see tiny little lances, very beautiful when seen under the microscope, shooting hither and thither on the surface of the water. If it is cold enough to make ice in the sunlight the crystal lances will glow with all the colors of the rainbow, and, as they dart about, the rapid changes of color will remind you of the wonders of the kaleidoscope. As the water continues to chill, the little lances come together, and then smaller and still more delicate crystals will be seen forming between the lances and welding them together. This process goes on until the surface is covered with a beautiful film of ice hardly strong enough to bear the weight of a mosquito. But the process goes on under this superficial layer, and a smooth and solid surface is the result.

Water is affected by changes of temperature differently from all other liquids. It seems to be a natural law for all liquids to expand in proportion to their increase in temperature, but there is a strange exception to the rule in the case of water. For example, take a quantity of water when exactly at the freezing point, 32 degrees above zero, and place it over a fire. As the temperature rises the volume will contract, contrary to the rule, until the water is about seven degrees warmer than it was at the beginning of the experiment. At that point, however, there is a sudden change. Contraction ceases, expansion begins, and the volume increases until the water is converted into steam.—*Pittsburgh Dispatch.*

DIAMONDS CAPABLE OF ABSORBING LIGHT.—A recent issue of the *Journal* of the Franklin Institute contains a paper on precious stones by Mr. George F. Kunz, who describes some exceedingly interesting and beautiful experiments on phosphorescent diamonds which he was enabled to make in Paris during the Exposition, through the courtesy of prominent scientific men. A dark room was provided, in which was placed a collection of over 150 diamonds. In a side of the wall a lens was inserted, and outside of the room a new alternating arc lamp of the Thomson-Houston system was hung. The lens, which was employed to concentrate the light, was covered

with a violet colored glass, so that the only ultra violet rays fell on the gems, of which but three of the entire number proved to be phosphorescent. All the others assumed a beautiful violet tint. The two stones whose phosphorescence were most marked were perfectly transparent white stones, one having a bluish tinge. Mr. Kunz says: "The phosphorescence exhibited by these stones was extremely beautiful; it remained visible when a metallic cap was put over the lens—gradually losing its intensity, however—for 15 minutes after the exposure." All the other stones were invisible in the dark.

Romance of the Sky.

By the increased power of telescopes, the number of stars within our ken has been increased from 2000, the number which may be seen in both hemispheres by the naked eye, to probably about 80,000,000. The star nearest to the earth, α Centauri, is about 275,000 times as far from us as the sun is, and Sirius is about twice as far away as that; if, however, we could view these bodies at an equal distance, α Centauri would appear nearly twice as bright as our sun, and Sirius 40 times as bright.

Star 61, Cygni, has a velocity of not less than 30 miles a second, or 3,000,000 miles a day. So far, then, we find that the stars are at different distances; that they are of different sizes, and that, instead of being fixed, they are all in movement.

Such bodies are masses of glowing gas, the materials of which are, for the most part, precisely the same as those of which our earth is built up, the great difference between such stars and the earth at the present time being that they are hot, while the earth is cold.

The sun is so hot at present that its outer atmosphere, instead of being composed of cool oxygen and nitrogen and water vapor, as happens with our own, consists of brightly shining hydrogen gas and iron vapor chiefly. The iron is not solid and it is not molten, but exists as iron steam at, perhaps, a distance of 200,000 miles above the shining orb that we see and call the sun. This, I think, may be taken as a fair indication that the sun is a very hot body, especially when we remember that as its center is approached, the temperature must always increase.

I have said this much about the sun, because it is very natural to ask whether all stars are like the sun. It used to be thought that they were, but I, for one, do not think this is so. When we come to examine the bodies which shine in the sky, those dim patches of gray light called nebulae, as well as many of the stars themselves, the prism tells us that the light which they send to us is very different from the light sent to us by the sun and by other stars, the light of which is exactly like sunlight.

A great deal of work recently done shows that probably many stars, instead of being like the sun, are built up, as the comets are, of enormous clouds or swarms of little bodies, some of them, perhaps, no bigger than grains of dust, the different quantities and qualities of the light given out depending upon the motions of these little particles and the average distance between them.

So, when we have a great many of these little masses closely packed together and moving rapidly, they will have an opportunity to strike one another and thus produce light and heat in a greater degree than can happen in those other so-called "stars," where the dust is sparser and the motion less rapid.

This is an idea which has lately been suggested, and I refer to it here because it appears to make clear a great many points on which children even of a larger growth have long been puzzled.

In this way, we pass from what we see in the heavens as patches of milk-white light, called nebulae, to other bodies even hotter than our sun, and when the stage is reached in which we see specks of light merely, and deal with "stars," properly so called, we get a hot body which increases in temperature as all the little particles arrive at the center, until the motion of all of them has been changed into heat, and a ball of vapor results, very, very hot.

As soon as the supply of heat ceases, the mass begins to cool. Our sun is such a cooling mass. The cooling goes on until at last a body such as our own earth is formed. This is why it is that the chemical composition of the sun and earth are so similar.

If this is what really happens, we can easily explain the colors of all the stars. Each stage of heat in a star has its own special color. It is true that sometimes very nearly the same color is produced at two different stages of heat; but aside from this, we know that very white stars are at the condition of their greatest heat, and that yellow stars are cooler, though some are old, some young; and that very red, but especially blood-red stars, are tottering on the verge of invisibility, having run through all their changes.—*Norman Lockyer.*

HEAT AND THE ELECTRIC CURRENT.—Cold copper wire offers less resistance to an electric current than a hot wire. The resistance increases at the rate of about one-fifth per cent for each Fahrenheit degree of rise in temperature.

A SWEDISH engineer claims to have invented a new machine for making horsehoe nails out of iron rods, the machinery making 140 strokes per minute, each stroke producing two nails,

ELECTRICITY.

Device for Protection from Accidental Heavy Currents.

Mr. Albert Barrett, electrician of a telephone company in Kansas City, has invented a device for protecting telephone and other wires from heavy currents, as when a telephone wire falls across a badly insulated electric light conductor or the trolley wire of an electric railway, in which cases the results are, as a rule, quite disastrous. To protect from these powerful wandering currents the necessarily delicate and expensive mechanism employed in telephone and telegraph systems, is a problem to which a number of electricians have devoted so little time. The invention in question forms a cut-out which is said to be operating satisfactorily, and is employed, it is stated, quite extensively on the switch-boards in that city and at many other points. The construction of the cut-out is quite simple. The line wire is cut and each of the two ends is fastened to the binding-screws. A very fine German silver fuse wire connects the binding screws. The fuse wire is arranged in a peculiar manner. Before being put in place it is passed through and by means of a little drop of wax molded on to, so to speak, a small loop of cord. The loop of cord is passed up through an eye and, as the drop of wax is a little larger than the eye, serves to hold down a spring. The operation of the cut-out is as follows: The moment a current of dangerous volume passes through the fuse wire, the wax button holding the loop and spring in place, melts. This action sets free the spring and the quick jerk of the loop through which the heated wire passes, breaks the latter.

A Lightning Arrestor.

Another device, the invention of Elihu Thompson, of Lynn, Mass., grapples even with the lightning of the clouds, and arrests even the most powerful current of electricity, in such a manner as to cause it to pass off harmlessly, even where there is no lightning rod to guide it to earth.

This instrument is based on the principle that where the discharge spaces in an arrester are in series and of a total length when added together, equal to several times that over which the discharge could pass if caused to leap across the single pair of discharge plates in an ordinary lightning arrester, there is secured not only freedom of discharge of current but at the same time freedom from the formation of and continuance of arcs between the discharge surfaces. In other words, Prof. Thompson finds that when a discharge has taken place, and the potential of the line is such as would tend to maintain an arc at the breaks, the potential can readily be made insufficient to do so by multiplying the number of striking spaces. He also finds that an arc is much more readily maintained between two plates with a single wide space than between a succession of discharge points or over a succession of spaces placed in series.

This device can be made effective for any current, however powerful, by simply increasing the number of discharge or jumping points. By causing the necessity for a constant jumping of the current, it virtually becomes perfectly discouraged, as it were, and its strength is dissipated by the great number of hindrances thus placed in its path. It is thus that inventors are gradually reaching out and surrounding the now dangerous power by safety devices so numerous and so effective that electricity will soon become the most safe, as well as the simplest power, which men can employ.

ELECTRIC ROADS PAY.—It is a noteworthy fact that nearly all the roads throughout the country which have adopted electricity as their motive power have increased their business, and many of them are extending their rails. This is good evidence that such roads are paying investments. The Waterville and Fairfield road, in Maine, is reported to have nearly doubled its business since it commenced operating by electricity. The increase in business of the Boston West End Company, according to the statement of its president, has been over 30 per cent. Electric railroads have come to stay.

ELECTRICAL UTILIZATION OF INSECTS.—An electric apparatus supplies a strong light which attracts the insects and moths; a suction fan worked by the electric current draws them in when they approach the light and carries them into a small mill, also worked by the electric current, where they are ground up and mixed with flour, and thus converted into poultry food of excellent quality. This is said to be a Bavarian contrivance.

TO REDUCE THE BRILLIANCY.—The brilliancy of the incandescent electric lamp is often a serious objection to its use, and a very simple method of modifying its dazzling glare has been suggested. All that is necessary is to dip the glass in a saturated solution of alum and water, and then apply, when dry, a coat of collodion as a protection. This is said to make the light very soft and agreeable, even to the most sensitive eyes.

The San Francisco and San Mateo Railroad Company has let a contract for 16 miles of steel rails to the Pacific Rolling Mills of this city.

GOOD HEALTH.

HEALTH OF THE STATE.—The State Board of Health for April reports: Mortality from 67 cities, towns and localities, having a population of 674,830, show 1064 deaths to have occurred from all causes. This is a percentage of 1.57 per 1000 per month, or 18.84 per 1000 per annum. Consumption was the cause in 164 cases, pneumonia in 153, bronchitis in 40 and congestion of the lungs in 8. Diarrhoea and dysentery are assigned as the cause of 7 deaths, cholera infantum 3, and of other diseases of the stomach and bowels 51. Croup caused 21 deaths, scarlatina but 1, whooping cough 3, typhoid fever 14, malarial fever 3, cerebrospinal fever 6, cancer 29, erysipelas 1, heart disease 63, alcoholism 13, and all other causes, not necessarily classified 436. Of this last number la grippe is responsible for 13 deaths, and there is a reasonable presumption that many fatal cases of lung disease are traceable directly to an attack of that disease. Diphtheria caused death in 48 cases, San Francisco furnishing 27. The deaths reported for cancer were 29, 16 of which occurred in San Francisco. It should be borne in mind that reports are received from only a little over one-half the population of the State. The only disease that may be said to prevail extensively is la grippe, 363 cases being reported from different parts of the State with an accredited fatality of 13. San Francisco, Los Angeles, San Diego and other southern points of importance report none at all. Oakland, Alameda and San Jose are almost, if not altogether, exempt. The progress of this remarkable malady has been somewhat erratic, following no well-defined course and requiring no unusual local conditions for its development.

EFFECT OF COLD WEATHER ON THE AGED.—The recent cold weather in Europe serves to strongly illustrate the inability of the aged to withstand exposure. A recent number of the *London News* states that in the second week of December, 1890, the number of deaths among persons 80 years old reached 100, while during the following three weeks, which were so unprecedentedly cold, the number increased to 116, 142, 148. In persons afflicted with diseases of the throat and chest, the average was doubled. While the fact that such severe weather is unusual there, and that people were not prepared to meet its rigors, accounts in a degree for the high rate of mortality, reference to the returns of our Philadelphia Board of Health shows that the rate here, where cold weather is not unusual, is decidedly higher in the colder months (in the months of January, February and March) than in the warmer months. It is of the utmost importance that aged people expose themselves as little as possible during extremely cold or inclement weather, and when necessity compels them to do so, that they shall be protected. No doubt, if the increased danger were sufficiently insisted on, in spite of the difficulty in making the average octogenarian realize that he is no longer young, the lives of many of the aged people would be greatly prolonged.—*Ez.*

HOW TO READ THE TONGUE.—The perfectly healthy tongue is clean, moist, lies loosely in the mouth, is round at the edge, and has no prominent papillae. The tongue may be furrowed from local causes or from sympathy with the stomach, intestines or liver. The dry tongue occurs most frequently in fever, and indicates nervous prostration or depression. A white tongue is diagnostic simply of the febrile condition, with, perhaps, a sour stomach. When it is moist and yellowish-brown, it shows disordered digestion. Dry and brown indicates a low state of the system, possibly typhoid. When the tongue is dry and red and smooth, look out for inflammation, gastric or intestinal. When the papillae on the end of the tongue are raised and very red, we call it a strawberry tongue, and that means scarlet fever. Sharp, pointed, red tongue will hint of brain irritation or inflammation, and a yellow coating indicates liver derangement. When so much can be gained from examination of the tongue, how important it is that the youngest child should be taught to put it out so that it can be visible to the uttermost point in the throat.

A SEED TAKING ROOT IN A STOMACH.—A New York paper vouches for the improbable story that a New York boy suffered such intense pain in his stomach that a surgical operation was decided upon to remove the cause. On opening that organ the trouble was found to proceed from an orange seed lodged at the junction of the large and small intestines. The seed was greatly swollen and had a sprout an inch long. The boy stood the operation well; but upon his return to consciousness, he asked to see the cause of his suffering, and said it did not look one-tenth as big as it felt, and even laughed feebly at the idea of "an orange tree starting to grow inside of him." He rested easily after that, and it was thought he would get well, but peritonitis set in and he died the next day.

An ordinary transparent glass globe absorbs about 10 per cent of the light passing through it; ground glass absorbs 30 to 45 per cent, and opal glass from 50 to 60 per cent.

The brain of an elephant is remarkably small, not more than 1.23 as large as that of a human being in proportion to the weight of both.

USEFUL INFORMATION.

THE BREATHING OF A LOCOMOTIVE.—The "breathing" of a locomotive—that is to say, the number of puffs given by a railway engine during its journey—depends upon the circumstances of its driving wheels and their speed. No matter what the rate of speed may be, for every one round of the driving wheels a locomotive will give four puffs—two out of each cylinder, the cylinders being double. The sizes of driving wheels vary, some being 18, 19, 20, and even 22 feet in circumference, although they are generally made of about 20 feet. The express speed varies from 54 to 58 miles an hour. Taking the average circumference of the driving wheel to be 20 feet, and the speed per hour 50 miles, a locomotive will give, going at express speed, 880 puffs per minute, or 52,800 puffs per hour, the wheel revolving 13,200 times in 60 minutes, giving 1,056 puffs per mile. Therefore, an express going from London to Liverpool, a distance of 201½ miles, will throw out 213,048 puffs before arriving at its destination. During the tourist season of 1888 the journey from London to Edinburgh was accomplished in less than eight hours, the distance being 401 miles, giving a speed throughout of 50 miles an hour. A locomotive of an express train from London to Edinburgh, subject to the above conditions, will give 423,456 puffs.—*London Iron.*

UNITING LEAD PIPE.—What may be found a convenient method of uniting the ends of pipe, the *American Engineer* thus explains: Whatever the size of the pipe may be, procure a block of hard wood, say four or five inches long and four inches in diameter, bore a hole straight through the center, so nearly the size of the pipe that the block can be driven on the end of the pipe with a light hammer. If one has a set of augur bits, it will not be difficult to select a bit of the proper size to make a water-tight fit. Let the block be driven clear on the pipe so that the end of the pipe will be flush or even with the end of the block. Now place the two ends of the pipe together and drive the block off one pipe on to the other, until the joint will be at the middle of the block. If the hole in the block is made of the proper size, the block will fit so closely that the joint will be water-tight; and if the ends of the pipe are dressed off true and square, the joint will be so strong that it will sustain the pressure of a head or column of water 100 feet high. Iron pipe may be united in the same manner. Should the joint leak a trifle, let shingle nails be driven into the wood around the pipe so as to press the timber firmly all around the pipe.

WHY BLOOD TIN RUSTS.—Tin plate is made by coating sheets of iron with a layer of tin. The best kind is known as black tin, being that which is covered with the thickest layer of tin and afterward hammered upon a polished anvil, in order to consolidate the coating and make it adhere more firmly. On being exposed to the action of the air, pure tin is not affected at ordinary temperatures. As soon, however, as a portion of the tin is removed by injury so as to expose even a tiny speck of iron surface, corrosion at once sets in and proceeds very rapidly. The reason of this is of an electrical nature. Iron and tin together form what is called a "galvanic couple," which will decompose the water (charged with carbonic acid) deposited upon them from the air. Oxygen and hydrogen gases are liberated, and the iron, having the greater affinity for the oxygen, is the metal attacked. Such corrosion is very rapid when the exposed iron surface comes in contact with water highly charged with carbonic acid in a mineral water factory.—*Mineral Water Review.*

NEW DECORATIVE PROCESS.—A new process by which artistic designs can be photographed on paper, cotton cloth, velvet and other fabrics, is becoming the "rage" in England, as any lady can, by its means take any white fabric and print upon it designs to suit her own taste, and in which pressed leaves will serve instead of a transparency for the production of many effects. At a recent meeting of the Photographic Society, England, a well known photographer printed different leaf patterns upon different parts of a piece of white cotton cloth. He then developed the different patterns with various developers by applying each of the latter locally with a brush; the result was a pretty series of designs in variegated colors upon one piece of cloth. The colors at present obtainable by the use of developers in the process are red, orange, purple and maroon; by mixing the purple and orange developers an unsatisfactory kind of an approach to green is said to have been obtained. Developers to yield blues and greens with this process have yet to be discovered.

IMPROVEMENTS IN MANUFACTURING SPIKES. Some interesting experiments have been made in the manufacture of spikes, with a view to making a finished article by rolling the bar in such a manner that its width shall be the length of the spike, and in such shape that the spikes may be cut from it with shears, similarly as a cut nail is made, except that the head is made in the rolling process. In tests made by running through some steel nails that had been slowly heated for 2½ hours, the result showed that the mechanism might be adapted to the object aimed at.

ENGINEERING NOTES.

Enormous Force of Hydraulic Streams.

The enormous force of a stream of water forced from a hydraulic nozzle, under from 200 to 300 feet or more of pressure, as sometimes used in hydraulic mining in this State, is something almost beyond belief. The quantity of water passing through these nozzles in a single day of mining is immense. A stream of 400 feet vertical pressure delivers a blow of upwards of 500,000 foot pounds—equivalent to about 1000 horse power.

Louis Glass, who for 16 years was superintendent of one of the large mines in this State, states that he has seen an eight-inch stream, under 311 feet of vertical pressure, move in a sluggish way a two-ton howler at a distance of 20 feet from the nozzle, and that the same stream, striking a rock of 500 pounds, would throw it as a man would throw a 20-pound weight. "No man that ever lived," adds Mr. Glass, "could strike a bar through one of these streams within 20 feet of discharge, and a man being struck by such a stream would be pounded into a shapeless mass." Mr. Augustus J. Bowie of this city, the author of a standard book on hydraulic mining, says it would be absolutely impossible to cut such a stream with an ax, or to make an impression on it with any other instrument. Mr. Bowie adds that, although never to his knowledge has a man been struck by such a stream as it comes from the pipe, several accidents have occurred where miners were killed by very much smaller streams at distances of 150 or 200 feet from the nozzle.

Prof. Christy says he has often tried to drive a crowbar into such a stream; and it felt as solid as a bar of iron, and, although he could feel the point of the crowbar enter the water for perhaps half an inch, the bar was thrown forward with such force that it was almost impossible to retain it in the grasp. An ax swung by the most powerful man alive could not penetrate the stream; yet it might be cut by the finger of a child, if the child were seated on a railway train moving parallel with the stream in the same direction and with the same velocity. That velocity would be considerably more than a mile a minute.

The statements presented in the above summary will not astonish engineering experts; the average citizen, however, is accustomed to regard water as the least destructive liquid that can be put in motion, and he is familiar with no stronger manifestation of its power than the velvety touch of a stream from the city faucet.

It might occur to a military man that such a powerful agent might be made a most terrible military agent for offense or defense, at short range, if it could only be brought to bear, as indeed it might be by a powerful steam-engine in a beleaguered fort or on board a battle-ship with an enemy close alongside.

THE PROPOSED IRISH CHANNEL TUNNEL is still a topic for discussion among English engineers. There seems to be no fear in this case that the tunnel might be made the route for invasion by a foreign army, although when the tunnel beneath the English channel was under discussion the idea that in time of war the tunnel might be a convenient means for invading England proved an insurmountable barrier to the enterprise. Besides the proposed tunnel, for which four routes have been suggested, there have been proposals to build a submerged tubular bridge about 60 feet below the surface of the water, a causeway after the fashion of a breakwater, and a series of great cantilever spans like an extended Forth bridge. The tunnel, however, seems the most feasible plan for making the crossing, and its cost is estimated at from \$25,000,000 to \$50,000,000.

THE CANADIAN PACIFIC was the first railway company on this continent to control and operate a through transcontinental line from ocean to ocean. It is now the first of the lines to the Pacific Coast to secure an entrance to New York City. The effect of this new route for freight traffic to the Northwest remains to be seen. As it has direct and short water communication between its western terminus and this city and Oregon, it goes without saying that it cannot fail, under existing custom-house regulations, to interfere more or less with the legitimate business with our own roads. A road built almost exclusively by Government aid and run in the interest of its Government must prove a most successful rival to any road built and operated by individuals.

YEARS ago competition in the way of swift ocean passages was between sailing vessels instead of between steamships. Then it was the "Yankee" clippers beat the world, and the recent passage of the clipper *Saint Paul* from Queensland to New York in 16 days shows that the making and handling of sailing vessels is not among the lost arts.

AN IMMENSE MOUNTAIN BRIDGE.—A bridge has recently been completed on a Peruvian Central Railway which spans a chasm with almost vertical sides and 235 feet in width. The bridge is of wrought iron and of the cantilever type, supported on two iron towers. Its total length is 575 feet, its suspended span being 105 feet long.

Passing Events.

Adhering to our custom, we write the above heading in the plural, though there is this week but a single event worthy of a place in this department of our paper. This portentous accident has not as yet transpired, but as we write it impends, and in another hour or two it will have been precipitated with all its momentous consequences. A couple of hrisers are on the eve of entering the fistic arena, and may even now be engaged inflicting on each other a well-deserved maning. At least half the community stand agog, waiting the result of the pummeling with breathless anxiety. Unfortunately, however, terminate the sorim-age as it may, neither of the men engaged in it will be apt to kill the other, and thus will society be exposed to be some day further equalized by another set-to between these hrutes.

But for this occurrence a number of news items would this week have claimed attention, such as the formation at Cincinnati of a third national party, the pursuit of the Itata, the revolt in Chilli, the wide-spread labor troubles here and elsewhere, not to mention various

other happenings of general interest. In the presence of this supreme event minor matters may, however, well be ignored. Next week, when ordinary affairs shall have recovered from the obscuration of this overshadowing transaction, when the current of business shall have unhindered to its usual channels and all things have become normal once more, we shall go on recording the outstanding occurrences of the day after the manner heretofore practiced, unless, to be sure, another prize fight should meantime obtrude itself on public attention!

A Glance Over the Mining Field.

As with our agricultural and most of our other leading industries, the business of mining in California is in a generally thrifty condition; not for a long time, in fact, has the outlook at this season of the year been more auspicious, this being especially true of quartz and hy-dranlic mining, these being so largely dependent on an ample water supply, which just now seems assured. The ground is full of moisture, the streams are already well replenished, and there is a good stock of snow on the mountains, which, the cool weather tending to conserve, will be likely to hold out far into the summer.

From our main gold-field favorable reports come to hand all the way from Siakiyon to San Diego, accounts from the lateral belts and the outside districts being equally satisfying. Whichever way we turn, the condition of the mining industry seems to be good and the outlook encouraging.

One year ago the state of affairs was quite different. The rivers, flooded by the heavy rains of the preceding winter, had swept away many of the dams, wheels, sluices and other portions of the miner's plant, the torrents descending from the mountains having destroyed large sections of his ditches and flumes. Before this damage could be repaired a good portion of the working season had in many instances gone by, the destruction of these works having in some cases been so complete that no attempt has since been made at repairing them. This year but little damage having been caused by high water, mining operations have nowhere been seriously delayed, having, in fact, been started up quite as early as usual, and as before remarked, under conditions pointing to an active and prosperous season.

Besides much new work likely to be undertaken in the department of vein mining, a decided impetus has been given of late to drift operations, the partial cessation of hydanlic washing having had a tendency to promote this branch of mining, the field for which is boundless and very inviting. So far from being exhausted or even seriously depleted, the old Pliocene channels of California, the principal sites of drift operations, remain almost virgin. We can mine along these channels for a hundred years, with just as good results as have here been reached in the past. It is indeed a notable fact that the returns from our "Dead Rivers" have for many years been growing better and better. We have in this line of mining no recent failures to record.

Passing over the Sierra Nevada, we come into a region where many of the conditions are unfriendly to mining, and where the history of the business is not, as a whole, a pleasant one to contemplate; yet even here this industry is being placed on a better footing, more than a thousand miners making good wages along the slopes of the Inyo range, where now, through the practice of carefully assorting or concentrating their ores, they are able to ship them in large quantities with profit. The silver mines over on that side, both at Calico, the principal district, and at other localities where the ores are reduced on the ground, are yielding fairly, and some of them remarkably well.

And this trans-Sierra is the territory of our borax-heds. Here in the depths of the deserts has been built up a quiet industry devoted to the manufacture of that strange but valuable salt, one of the peculiar products of that arid and sterile region, and here only on the Pacific Coast is soda made and refined in large quantity. Under the lee of this Inyo range, one of the most extensive granite quarries in the State has been opened, and is now being largely and successfully worked, the stone—capable of being gotten out in immense blocks—being of superior quality.

Looking again to the seaward side of the

Sierra we find here too this class of secondary mining industries actively and successfully prosecuted. Our cinnabar deposits, though not yielding as bountifully as in former years, are still the largest quicksilver producers in the world, and to their owners a source of considerable wealth. These mines are being worked constantly but in a moderate way, a steadily declining output admonishing to a careful husbandry of their resources. With snob diminished product and prospective dearth coupled with an increased demand for quicksilver it seems strange that the Altona deposit, the richest in the State, should be suffered to lie idle, now that the legal complications that so long prevented its being worked, have been settled and disposed of. The little capital required to restore the Altona mine to a profitably productive condition ought to be had at a day's notice.

After a long interregnum copper mining in California is again coming to the front. The Copperopolis group of claims, including the once prolific Union property, has within the past two years been rehabilitated; the underground workings having been nwatered, the reduction plant reconstructed and its capacity largely increased, active operations on the several smaller mines have been located elsewhere in the State, having meantime been continued. The probabilities are that our output of this metal will be much larger the present year than it has been for the past 20 years or more, during which the annual average has been less than a 1000 tons of ore or its equivalent in matte and regulus, hardly a quarter of what this year's product will amount to.

Our petroleum, asphaltum, salt, cement and lime interests are in like manner being fairly well prospered, while our stone and slate quarries are doing a large and thrifty business. In short every branch of mining in California is in a tolerably good condition, many of them better than ever before.

Rediscoveries in the Mining World!

There appeared in the last issue of the PRESS some editorial remarks on the Deep Creek country, Western Utah, now a locality of considerable interest in a mining point of view. Since writing that article we find that these Deep Creek discoveries are within the boundaries of what was formerly known as the Schell Creek district, the site of a very pronounced mining boom in the summer of 1872, nor do we know but that these discoveries are coincident with those made at that time.

Going back a little, it may be remarked, that on the collapse of the White Pine excitement in 1870, most of the prospectors who had been allured into that region scattered in various directions, some returning whence they came, but more making their way into the country adjacent on the south and east, there to prosecute their search after the rich mineral deposits they had hoped to find in and about Treasner Mountain.

Prosecuting their labors in the quarter indicated many auriferous lodes were discovered, and a number of mining districts organized during the following two or three years, principal among these being the Robinson, Schell Creek and the Fabranegat with others of lesser note. To none of these districts was there such a rush as to Schell Creek, toward which the emigration setting in during the spring of 1872, culminated before the autumn of that year, the life having gone out of the boom within a twelvemonth thereafter. While it lasted, however, matters here were very lively.

A town named after the district was laid out on the old Overland stage road, which here, after crossing Deep creek, followed up a long canyon that by an easy ascent reached nearly to the summit of the Schell Creek mountains, a low, sparsely timbered range lying to the east. At the entrance to this canyon, where it opened out into a little flat, the Overland Company had a station with some stables and a comfortable adobe house. In the furor for laying out new streets, this house, the only substantial structure in or near the place, was demolished to make way for the new thoroughfare, which it was held should not deviate a hair's breadth from a straight line. In this same spirit were all the improvements in the incipient metropolis projected and to some extent carried out, several fine buildings having been erected to serve the

various uses incident to pioneer mining towns.

A good deal of work was done on the mining claims taken up and generally with encouraging results, but the ore extracted, though of good grade, would not bear transportation to reduction works or a market, there being no mill in the district for working it. Well's Station, on the Central Pacific railroad, was away 75 miles to the north, Hamilton 80 miles to the west, while Salt Lake City was 130 miles to the East, these being the nearest points at which there existed any works for reducing the ore or facilities for shipping it by rail. The miners being under heavy expenses and unable to realize anything from their ores, were compelled to leave the district, which, by the end of 1873, had been almost wholly vacated.

If now, as reported, some rich metalliferous deposits have been found in the Deep Creek country, it is not matter for surprise, nor can snob finds be considered altogether new. As has frequently happened, this may be but another of those reanreations into life of what was before considered dead. Looking over the history of mining discovery on this coast, it does seem as if the labors of the pioneer prospectors were destined to a first failure. We are told on good authority that except the seed die it cannot be quickened into life; and so with the seed sown by these early explorers of our mineral domain; though much of it fell in stony places and dies, much after a timesprings up and yields an abundant harvest.

It is the onatom to speak lightly of this class of men, who, having, like these adventurers into the White Pine mountains, failed in the primary objects of their visit, have scattered and drifted away over the deserts, there to encounter further disappointment, and finally abandon the field in despair. But not always has their labor and their research been in vain, as witness many now flourishing camps throughout our mining regions that have experienced this sort of second growth; the districts that have gone through this process of undue excitement, basty abandonment and ultimate regeneration, being especially numerous in Oregon, Washington, Utah and Nevada.

A Highly Commendable Movement.

Charles J. King acting Secretary to the State Board of Charities, in a printed circular, advises the friends and supporters of that cause that the bill creating a "State Board of Charities and Corrections" introduced into the California Legislature at its last session failed to become a law by reason of the pressure incident to the closing of the session. That snob should have been the case was very unfortunate, as this measure, had it been enacted into a law, would have done much toward abating vice and relieving the wants of the needy in this State, by imparting system and efficiency to the efforts being directed to that end. This institution, already organized, has a human as well as an economic side to it, the former being with many its chief recommendation, nevertheless, administered in the manner proposed, this institution could be made the means of saving many thousands to the State annually, wherefore it behooves our people to see that the bill above mentioned be passed at the next sitting of the Legislature. If there are philanthropists willing to devote their time and means toward forwarding such a beneficent scheme, the State can hardly do less than aid them to the extent requested.

Mr. King in this circular returns thanks to the Hon. W. C. Hendricks, former Secretary of State, for the much interest taken in this cause; also to Mannel Brocklebank, Esq., for like services rendered, the latter, as we all know, having talked much and well in behalf of the poor and the suffering both here and elsewhere.

MENDING SLOWLY.—Wm. Ireian Jr., State Mineralogist, does not, we are sorry to learn, meet with speedy recovery from the accident that befell him some six or seven weeks ago. Falling down a flight of steps at that time, his leg was broken between the thigh and the knee. Since then the sufferer has been kept on his back, unable to so much as move the injured limb, a position that has tried both his patience and his fortitude sorely. It will yet be a week or two before Mr. Ireian will be able to get about even on crutches.

Suspension Cableways.

The great rock and ore excavation at Tilly Foster, N. Y., has attracted an immense amount of interest among engineers and contractors. Through the courtesy of the Lidgerwood Manufacturing Company, the prominent hoisting engine manufacturers of New York, Chicago and Boston, we are enabled to present in this issue several interesting sketches, made by them, illustrating this property and the working of the suspension cableways—a superior system of hoisting and conveying.

Fig. 1 is a general view of the mines looking southwest.

Fig. 2 is a plan showing the location of the cableways and railroad tracks. The plan shows an opening 450 feet long by 300 feet wide on the top; the depth of the pit is about 300 feet.

Fig. 3 shows a cross-section near incline cableway No. 3 and the horizontal cableway No. 4. A year ago the No. 3 cableway was remodeled with the Miller patent and its working is much improved. The invention refers to the device which supports the hoisting or fall rope. It is shown in the smaller sketch and consists of a simple wood and iron carrier which follows the carriage down the incline until stopped by a small steel button secured to an auxiliary rope placed above the main cable. A second carrier stops at a large button farther down the incline.

The cost of operating these cableways is something less than \$8 per day, in the course of which an average of 150 trips can be made. Each load being about a cubic yard, makes the entire cost for hoisting, conveying and delivering five cents per ton.

In this work there are employed by the contractors, Messrs. Stephens & Arnold, about a dozen Lidgerwood hoisting engines of the latest improved pattern; in fact, with one exception, the Lidgerwood engine is used to the exclusion of every other kind.

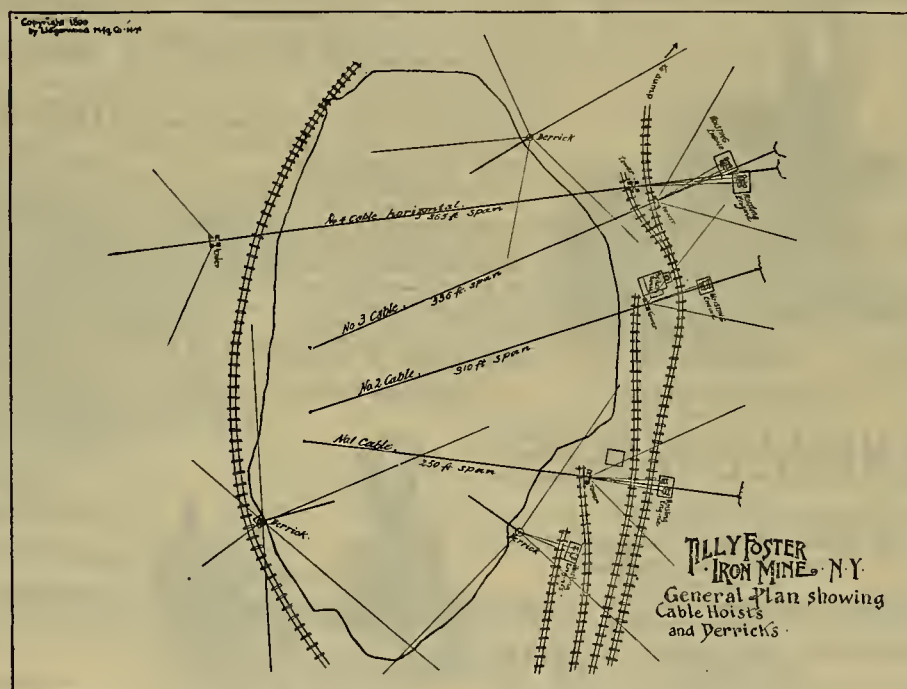

The cables were made by at least three different wire-rope makers. All the cableways, however, are under the patents controlled by the Lidgerwood Manufacturing Company. The illustrations were drawn by one of the Lidgerwood Manufacturing Company's staff of draughtsmen and are copyrighted.

AFTER THE WRONG PARTIES.—The San Francisco Board of Education has determined that the pupils in our public schools shall be punished only on the hand with a leather strap of prescribed weight and dimensions, many tedious preliminaries requiring to be observed before such punishment can be inflicted. Would it not be better to refer this question of punishment to be decided by the big boys in the school? Young America, as being the party most interested, certainly ought to be consulted in an affair of this kind; besides, this would be the most democratic mode of procedure. After all, it

might perhaps be the better plan to whale the teachers and let the pupils go.

LET IT BE ENFORCED!—Now that we have a law prohibiting boys under 18 years of age

from visiting drinking saloons, let the Chief of Police in this city see that it is rigidly enforced. Let the committing magistrate also make sure that offenders brought before him are punished to the full extent of the law.

A Good Time to Renew the Silver Agitation.

It would be thought that the present dearth of gold in England, Germany and Russia would bring the sticklers for monometallism to their senses! These countries have for several months past been heavy importers of gold from the United States, the exigencies of the situation being such that at last accounts they were still cashing for more; and unless something occurs to relieve the stringency of the money market, this metal must soon command a ruinous premium over there.

Formerly, when silver equally with gold circulated as money in these countries, there existed no necessity for such importation of either the white or the yellow metal. Now, with gold as the sole standard of value, there is constant trouble, there not being enough of this metal for the transaction of business, which has been all the while increasing, while the volume of the circulating medium has, through the demonetization of silver, been immensely curtailed. As the amount of business in these countries is constantly being augmented, this comparative scarcity of money must every year be more and more felt, as they do not themselves produce any great amount of the precious metals, nor is the balance of trade largely in their favor.

Under the circumstances, the present would seem to be an opportune time for our Government to renew its proposal for an international conference, for considering the expediency of restoring to silver its former monetary function, instead of continuing it, as at present, a mere commodity, to be bought and sold like any other on the market. While such measure would prove beneficial to all parties interested, it would be of less consequence to this country than any other, we being large producers of the precious metals, and having already adopted a policy nearly equivalent to the free coinage of silver, of which our mines turn out some \$63,000,000 annually.

Of the amount so produced, the General Government purchased every year about fifty-four millions for coinage, leaving only nine millions for consumption in the arts. It appears, then, that we mint and otherwise use up all the silver we produce, wherefore we are not greatly concerned about the enactment of a law establishing its free coinage in the United States.

We are now realizing about all the benefits that would result from the establishment of such a measure, still, if the rehabilitation of silver could everywhere be brought about, it would prove a very desirable movement as tending to settle its status on a satisfactory and permanent basis. And it is in the hope of being able to bring this about that our Government should at this auspicious period seek to co-operate with these European nations to that end.

The demonetization of silver has proved a mistake all around, and we, as the largest producers of that metal, should hasten to repair it. Not that we are suffering from this mistake greatly more than most other peoples, but because, while it is hurting us some, sound policy requires that some general understanding should be reached as to our future dealings with this troublesome question.

THE CORNUCOPIA OF THE WORLD!—A year of plenty awaits us; prosperity smiles over all the hills and plains of California; we are about to gather a rich harvest of fruits and grains and gold, such as has hardly ever in the past brought reward to our people. For weeks the strawberry vines have been yielding abundantly, and now the cherries, large and luscious, are going forward to distant markets. A wide acreage of the cereals shows a good growth generally, the fruit trees almost everywhere being so overburdened that they call for support; the pasturage is luxuriant and the flower gardens are "oppressed with perfume." Peace and abundance dominate the land. Little trouble is in this cornucopia of ours, save the antagonisms between employers and workmen, and for these there is such scant just cause that they ought to meet with speedy removal. The former are the best served and the latter the best paid of any like classes in the world; wherefore, then, this everlasting wrangle? It ought to cease, and would if the wage-earner here could be made to appreciate the many advantages he enjoys over the workmen of most other countries.

VALUABLE BOOKS ON Painting, Varnishing, Etc.

A Practical Treatise on the Fabrication of Volatile and Fat Varnishes, Lacquers, Siccatives and Sealing Waxes. From the German of Erwin Andros, Manufacturer of Varnishes and Lacquers. With additions on the Manufacture and Application of Varnishes, Stains for Wood, Horn, Ivory, Bone and Leather. From the German of Dr. Emil Winkler and Louis E. Andros. Translated and Edited by Wm. T. Brant. Illustrated. In one volume. 346 pages, 12mo. Price \$2.50.

A Complete Guide for Coach Painters. Translated from the French of M. Arlot, Coach Painter, for 11 years foreman of painting to M. Eherler, Coachmaker, Paris. By A. A. Pesquet, Chemist and Engineer. With an appendix on the materials and the practice of Coach and Car Painting and Varnishing in the United States and Great Britain. 12mo. Price \$1.25.

A Practical Treatise on the Manufacture of Colors for Painting. Comprising the Origin, Definition and Classification of Colors; the Treatment of the Raw Material; the Best Formulae and the Newest Processes for the Preparation of every Description of Pigment, and the necessary Apparatus and Directions for its Use; Driers; the Testing, Application and Qualities of Paints, etc. By MM. Riffault, Vergnaud, Toussaint and M. F. Malepere. From the French by A. A. Pesquet. 30 engravings. 8vo. Price \$7.50.

A Practical Manual of House Painting, Graining, Marbling, and Sign Writing. With nine Colored Illustrations of Woods and Marbles, etc. By E. A. Davidson. 12mo. Price \$3.

Painter, Gilder and Varnisher's Companion. Containing Rules and Regulations in everything relating to the Art of Painting, Graining, Varnishing, Glass-Staining, Graining, Marbling, Sign-Writing, Gilding on Glass and Coach Painting and Varnishing; Tests for the Detection of Adulterations in Oils, Colors, etc. Sixteenth Edition, revised, with an appendix. Containing Chevreul's Principles of Harmony and Contrast of Colors, etc. 12mo. 356 pages. Price \$1.50.

Sign-Writing and Glass-Embossing. A complete, practical illustrated Manual of the Art. By James Callingham. 12mo. Price \$1.50.

The Painter's Encyclopedia. Containing Definitions of all important Words in the Art of Painting, with Details in Coach, Carriage, Railway Car, House, Sign and Ornamental Painting, including Graining, Marbling, Staining, Varnishing, Polishing, Lettering, Stenciling, Gilding, Bronzing, Scene Painting, Porcelain Painting, Plain Painting, Distemper Painting, etc. By F. B. Gardner. 150 illustrations. Price \$2.

Everybody's Paint Book. A Complete Guide to the Art of Painting, designed for the use of those who wish to do their own work. Practical Lessons in Plain Painting, Varnishing, Polishing, Staining, Paper Hanging, Kaleomining, etc., as well as Directions for Renovating Furniture and Hints on Artistic Work for Home Decoration, together with a Description of the Tools and Materials Used; Directions for Mixing Paints, etc. 33 illustrations. 12mo. Price \$1.

The Complete Carriage and Wagon Painter. A Compendium of the Art of Painting Carriages, Wagons and Sleighs, including Lettering, Scrolling, Ornamenting, Stripling, Varnishing and Coloring, with Recipes for Mixing Colors. 73 illustrations. 12mo. Price \$1.

Practical Graining. With Description of Colors Employed and Tools Used. Illustrated by 47 Colored Plates, representing the Various Woods Used in Interior Finishing. By Wm. E. Wall, Grainer. 8vo. Price \$2.50.

The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

Our new and revised Catalogue of Practical and Scientific Books, 87 pages, 8vo, and our other Catalogues the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish us with his address.

HENRY CAREY BAIRD & CO.,
INDUSTRIAL PUBLISHERS, BOOKSELLERS & IMPORTERS,

GREAT REDUCTION! BATTERY SCREENS.

Best and Cheapest in America.

PERFORATED SHEET METAL

For Flour and Rice Mills, Grain Separators, Revolving and Shot Screens, Stamp Batteries and all kinds of Mining and Milling Machinery. Iron, Steel, Copper, Brass. Zinc and other metals punched for all uses. Inventor and Manufacturer of the celebrated Slot Cut hurred and Slot Punched Screens.

Mining Screens a specialty, from No. 1 to 15 (fine). Orders promptly attended to.

San Francisco Pioneer Screen Works,

221 & 223 First St., San Francisco, Cal.

JOHN W. QUICK, Proprietor.

QUARTZ SCREENS

A specialty. Round, slot or hurred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

THE AIR BRUSH

Descriptive pamphlet sent free. It points out one way to earn a living. Address **AIR BRUSH MFG CO.** 9 Nassau Street, Rockford, Illinois.

PACIFIC ROLLING MILL CO.,MANUFACTURERS OF..... Cast Steel Castings and Steel Forgings

UP TO 20,000 LBS. WEIGHT.

True to pattern and superior in strength, toughness and durability to Cast or Wrought Iron in any position or for any service.

GEARINGS, SHOES, DIES, CAMS, TAPPETS, PISTON-HEADS, RAIL ROAD and MACHINERY CASTINGS of Every Description.

— ALSO —

HOMOGENEOUS STEEL, SOFT and DUCTILE, SUPERIOR TO IRON FOR LOCOMOTIVE AND MARINE FORGINGS.

ALSO Steel Rods, from 1 to 3 inch diameter and Flats from 1 to 8 inch. Angles, Tees, Channels and other shape Steel Wagon, Buggy, and Truck Tires, Flow Steel, Machinery and Special Shape Steel to size and lengths. STEEL RAILS from 12 to 45 pounds per yard. ALSO, Railroad and Merchant Iron, Rolled Beams, Angle, Channel, and T Iron, Bridge and Machine Bolts, Lag Screws, Nuts, Washers, Ship and Boat Spikes; Steamboat Shafts, Cranks, Pistons, Connecting Rods, etc. Car and Locomotive Axles and Frames, and Iron Forgings of all kinds, Iron and Steel Bridge and Roof Work a Specialty.

HIGHEST PRICE PAID FOR SCRAP IRON AND STEEL.

Orders will have prompt attention. Send for Catalogues. Address

PACIFIC ROLLING MILL CO., 202 Market St., San Francisco.

FULTON IRON WORKS, HINCKLEY, SPIERS & HAYES, Proprietors.

(ESTABLISHED IN 1855.)

Office, 213 Fremont St.,

San Francisco.

—MANUFACTURERS OF—

MARINE ENGINES AND BOILERS.—Propeller Engines, either High Pressure or Compound, Stern or Side-wheel Engines.

MINING MACHINERY.—Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

MILL MACHINERY.—Batteries for Dry or Wet Crushing, Amalgamating Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores, Water Jackets, etc.

MISCELLANEOUS MACHINERY.—Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Powder Mill Machinery, Water Wheels.

TUSTIN'S PULVERIZER.

Tustin's Pulverizer WORKS ORE WET OR DRY.

ENGINES AND BOILERS

OF ALL KINDS,

Either for use on Steamboats or for use on Land.

Water Pipe, Pump or Air Columns, Fish Tanks for Salmon Canneries

OF EVERY DESCRIPTION.

Boiler Repairs Promptly attended to and at very moderate rates.

GAS WORK A SPECIALTY.

MINING ENGINEERS.

EVERETTE'S MINING OFFICE.

Pioneer Mining Office of the Northwest Coast.

Having the largest permanent brick assay furnaces, chemical laboratory and mining office on the Northwest Coast with a collection of about 400 samples of the ores of Alaska, British Columbia, Oregon and the Northwest Territories, and having made personal examinations of nearly every mining camp on the Pacific Slope, from California to Alaska, I am prepared to do any class of legitimate and honest mining work, such as EXAMINING, ENGINEERING, SAMPLING and REPORTING ON THE VALUE OF ALL MINERAL, COAL and FIRE-CLAY PROPERTIES, BUILDING STONES, EARTHES, ASSAYS AND ANALYSIS OF ORES, WATERS, CHECK SAMPLES OF ORE, PULPS, "ORGANIC ANALYSIS" WORK, and in fact any work connected with the office of a first-class mining geologist and chemist. Any information mining men may desire to know relative to the MINERAL OR COAL RESOURCES of the entire Pacific Northwest will be honestly given. Address **Dr. WILLIS E. EVERETTE** Consulting Mining Geologist and Chemist, 1315 E Street, Tacoma, Wash.

A. S. GRANT, S. B. CONNOR

CONNOR & GRANT, Millwrights and Engineers

303 CALIFORNIA STREET,

Rooms 80 and 81, SAN FRANCISCO, CAL.

Designers and Constructors of Gold and Silver Mills Hoisting and Pumping Works, Tramways, and everything pertaining to the Mining and Reduction of Ores.

ROSS E. BROWNE,

Mining and Hydraulic Engineer,

No. 307 Sansome St., SAN FRANCISCO.

W. A. GOODYEAR, Civil and Mining Engineer, MINING EXPERT AND GEOLOGIST.

Address "Business Box A," office of this paper, San Francisco.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and absolutely water-tight. It is also used for cutting the fuses. They are readily gotten-up of the finest cast steel, nickel plated. Price, \$2 each, or the entire instrument finished in gold plate, \$5. N. W. MOODEY, Fresno, Cal.

The Best Mining District

On the Pacific Coast!

GRASS VALLEY, CAL.

THE BEST NEWSPAPER published in the district is

THE TIDINGS.

Daily and Weekly edition. Gives all the Mining News. Dealers in Mining Machinery and Mining Supplies will find THE TIDINGS the best medium for directly reaching the owners or managers of mines. Investors in mines will find it to their advantage to subscribe.

Many mines are in successful operation, and new enterprises are being instituted and many others are in contemplation.

DAILY, \$5.00 a year; WEEKLY, \$2.50, in advance.

PERFECT PULLEYS

First Premium Awarded at Mechanics' Fair, 1884. CLOT & MEESSE, Sole Licensed Manufacturers of the MEDART PATENT WROUGHT RIM PULLEY For the States of California, Oregon and Nevada, and the Territories of Idaho, Washington, Montana, Wyoming, Utah and Arizona. Lightest, Strongest, Cheapest and Best Balanced Pulley in the World. Also Manufacturers of SHAFTING, HANGERS AND APPURTENANCES. SEND FOR CIRCULARS AND PRICE LIST. No. 129 and 131 FREMONT STREET - - - SAN FRANCISCO, CAL.

THOMAS PRICE & SON,

Assay Office, Chemical Laboratory, BULLION ROOMS and ORE FLOORS, 524 Sacramento Street, San Francisco, Cal.

COIN RETURNS ON ALL BULLION DEPOSITS IN 24 HOURS. WORKING TESTS OF ORES BY ALL PROCESSES. SPECIAL ATTENTION PAID TO CONCENTRATION OF ORES. Ores Received on Consignment, Sampled, Assayed, and Disposed of in the Open Market to the Highest Bidder.

Metallurgy and Ores.

SELBY SMELTING and LEAD CO., 416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY And Assay Office. Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets. MANUFACTURERS OF... BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, Etc., Etc. ALSO MANUFACTURERS OF Standard Shot-Gun Cartridges, Under Chamberlin Patent.

JOHN TAYLOR & CO., IMPORTERS AND DEALERS IN ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES, ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS. 63 & 65 First St., cor. Mission, San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals. Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Agents for the Morgan Crucible Co., Battersea, England. Also for E. G. Dennison's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

Nevada Metallurgical Works. NO. 28 STEVENSON STREET, Near First and Market Streets, S. F. C. A. LUCKHARDT, Manager. ESTABLISHED 186

Ores worked by any Process. Ores Sampled. Assaying in all its Branches. Analyses of Ores, Minerals, Waters, etc. Working Tests (practical) Made. Plans and Specifications furnished for the most suitable Process for Working Ores. Special attention paid to Examination of Mines; Plans and Reports furnished. C. A. LUCKHARDT & CO., (Formerly Huhn & Luckhardt, Mining Engineers and Metallurgists

GOLD MINES —AND— STOCK IN MINES FOR SALE.

Dividend-paying Mines from \$150,000 up. Undeveloped Mines from \$10,000 up. Undeveloped Mines on Bond. Stock in Dividend-paying Mines from \$1 up. Stock in Undeveloped Mines now being opened from 25 cents up.

All situated in the GRASS VALLEY MINING DISTRICT, the Oldest Quartz Mining District on the Pacific Coast, and the Richest and most Permanent in the World. The mines of this district are practically inexhaustible, as nearly half a century of constant working is proof. Grass Valley has the deepest regular dividend-paying gold mines in the world, and the end is not yet, for these same mines are as rich to-day as at any time during their history. Gold mining, especially in Grass Valley, when under honest and scientific management, is one of the safest and most profitable of all American industries. It is a business that will return annually a profit of from 100 to 300 per cent on the investment. Mining is a science acquired only by years of study, combined with practical experience. Therefore, failure is the rule whenever the management is ignorant and unscientific. The undersigned is a practical scientific and successful miner, has made mining a life study and vocation, is honest and trustworthy, and will not, under any circumstances, recommend or deal in any but valuable paying property and properties that will develop dividend-payers. No Wildcat Mines; no Sharp Practice; no reasonable chance for loss; Honesty and Square Dealing Guaranteed. Correspondence solicited. Full particulars by applying to S. B. FOWLER, Supt. Hartery Mine, Grass Valley, Nevada Co., California. DEWEY & CO., PATENT AGENTS, 230 Market St., San Francisco, Elevator, 13 Front St.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, May 21, 1891.

The past week was characterized by favorable weather for growing cereal crops, but at the close it is turning off warmer which will hasten their maturing, but no bad result will follow unless we have hot north winds before harvest. The prospects for a large wheat crop are sending a larger fleet of vessels to this port than has been on the way at any one time for several years, but we will want them and more besides. The vessels coming will tend to keep the price of coal, iron, etc., down. The local money is fairly easy, but closer working is looked for when the crops begin to move.

MEXICAN DOLLARS—The market is dull at 77@77 1/2c.

QUICKSILVER—Eastern advices report a stronger market, but so far, ours do not respond. This is doubtless due to selling competition. Receipts the past week aggregate 395 flasks. The overland shipments in last month aggregate 810 flasks.

SILVER—Purchases by the Department are reported as follows in this month:

Date.	Offered ounces.	Purchased ounces.	Price paid per ounce.
May 1.....	739,000	350,000	\$.9780 to \$.9840
May 4.....	—	36,000	\$.9850 to \$.9870
May 11.....	—	593,000	\$.98125 to \$.9825
May 18.....	—	144,000	\$.97950 to \$.980
May 18.....	—	315,000	\$.9805 to \$.9830

The purchases by the Mint on Department days are irregularly reported by the associated press, making it difficult to form a correct idea when the monthly quota has been secured. The market is still low, but there is a gradual improving tone which goes far in strengthening the belief with financiers that higher prices will prevail before long. The surplus supply in this country is about exhausted, and as the European money markets are easing, many claim that speculators will draw to silver and to securities based on silver for an investment, which, combined with an increased call from India, will do no little in bringing about better prices. Another thing will have an important bearing on the market, viz.: The stand taken by reform parties in favor of remonetizing silver. This is emphasized by the National Union Convention just held at Cincinnati coming out in favor of the free coinage of silver. It now looks as if Congress this winter will remonetize the metal.

BORAX—Receipts the past week aggregate 498 cts. Shipments overland in last month aggregate 10,314 cts. The market is reported easing but no lower.

LIME—Receipts the past week aggregate 3775 hhls. The market is steady, with a good demand. The low price of lumber is stimulating building.

ANTIMONY—With increasing supplies at the East, New York advices report lower prices, with which our market sympathizes.

TIN—Imports the past week aggregate 3306 ingots from Australia and 1067 bxs. of plate from the East. The market is essentially unchanged. The consumption is enlarging. On July 1st the increased duty on plate goes into effect, and as iron and steel appear to have touched bottom, higher prices are certain to rule for plate, but pig tin will probably go lower as the duty on it will not go into effect for about two years yet, and in the manufacture of plate less than five per cent of tin is used, the rest (over 95 per cent) being either iron or steel.

LEAD—The local market is unchanged. At the East the market is reported steadier.

COPPER—The market continues weak. The Iron Age reports the New York market as follows: Consumption shows no sign of improvement, but production continues on a large scale, and it is no secret that there is considerable accumulation of stock at first hands that has more or less weight, despite the assumed indifference of the representatives of the chief producers. Export outlet, except for furnace material, is very narrow. Home consumers buy only as imperative wants necessitate, and the latter are neither extensive nor urgent. At 13 1/2c there seems to be more Lake Superior ingot available than an outlet for can be found at the present time. Arizona Ingot at 12 1/2c, is virtually a drug upon the market, and bids of 1/2c to 3/4c less for round lots would probably not go begging. On common casting brands anything above 11 1/2c is exceptionally high at the present time.

IRON—The market continues weak under liberal spot and to arrive stocks. English and Eastern advices are favorable to better prices.

COAL—Imports the past week aggregate as follows: Nagasaki, 3250 tons; Coos Bay, 450; Departure Bay, 2400; Tacoma, 4000; Seattle, 2250. Total, 12,350 tons. Increased offerings are reported for prompt and early shipments from Europe, the East and Australia. This is due to our large grain crop attracting to us more vessels, and they prefer bringing coal to coming empty. The spot market is easy with some kinds quoted lower.

COKE—Spot parcels are on the market at concessions. Consumers buy sparingly.

PERMANENT INSTITUTIONS.—There are many things that we in San Francisco are compelled to do without, but Dennis Kearney and the poor we always have with us, Dennis having lately returned from the East to stay.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING MAY 12, 1891.

- 452,333.—STREET RAILWAY RAIL AND PAYMENT—P. Bargion, S. F.
- 452,174.—GAS ENGINE ATTACHMENT—M. M. Barrett, S. F.
- 452,023.—DRAIN PIPE FOR BUILDINGS—J. L. Crittenden, Oakland, Cal.
- 452,102.—FRUIT-PICKER—Amalea Fogeli, Nevada City, Cal.
- 452,223.—HOUSE DOOR LETTER BOX—Emma C. Hudson, Seattle, Wash.
- 452,184.—POWER STREET PAVING MACHINE—F. A. Huntington, Oakland, Cal.
- 452,106.—WEATHER STRIP—A. La Jeunesse, Alameda, Cal.
- 452,233.—CLOTHES DRIER—J. McKinnin, Spokane Falls, Wash.
- 452,348.—BEDSTEAD TABLET—C. H. Murray, Portland, Or.
- 451,949.—SAFETY GRIP BRAKE FOR CABLE CARS—C. E. Naylor, S. F.
- 452,283.—HYDRAULIC AIR COMPRESSOR—W. R. Phillips, Seattle, Wash.
- 452,112.—RAZOR STROP—M. E. Reilly, Montezuma, Wash.
- 452,284.—DRIVING CALK—M. E. Reilly, Montezuma, Wash.
- 452,084.—DOOR MANIPULATOR—F. Schmitz, S. F.
- 452,091.—TREATING CONDUCTORS—J. B. Williams, Oakland, Cal.

The following brief list, by telegraph, for May 19 will appear more complete upon receipt of mail advices:

California—Ulrich Bachmann, San Francisco: apparatus for impregnating liquid with gas; Conrad Beyer, San Francisco: folding bed; Charles H. Coffin, San Francisco: three-wheeled vehicle; Charles C. Davis, Los Angeles: portable burglar alarm; Henry N. Elliott and E. L. Bemis, Los Angeles: suspender; William R. Finch, Eureka: breech-loading gun; Adam W. Gilfillan, steam boiler alarm; August Harding, Oakland: explosive engine; Charles P. Harris, San Francisco: game puzzle; Mary C. C. Hartman, Redding, steamer; Byron Jennings, San Jose: assignor of one-half to J. Brusie, Oakland, electric insulator; Byron Jennings, assignor of one-half to J. Brusie, Oakland, insulator holder for electric railway; Joseph F. McElroy, assignor of one-fourth to J. T. Delaney, San Francisco, desk and seat support; William A. McFarlane and S. A. Barrett, San Bernardino, water gauge; Austin D. Moore and A. K. Green, San Francisco, faucet; J. J. Pieter, San Francisco, athletes' supporter; George H. Tietjen, San Francisco, stencilizing machine; Walter R. Webster, Pine Grove, closing device for water-closet lid; Walter R. Webster, Pine Grove, spring hinge; Joseph S. Whitcomb, San Francisco, excavating apparatus; Alfred L. White and D. L. Miller, Sulsum, automatic pumping apparatus; James B. Williams, Oakland, insulated electric conductor; John J. Spelker, Sacramento, remedy for rheumatism, neuralgia and headache.

Oregon—Frank Vatter, Marshfield, apparatus for preserving piles.

Washington—Edward W. Mitchell, Spokane Falls, assignor of one-fourth to R. Parker, J. H. Stearns and B. F. Sutton, Brooklyn, N. Y., conductor for electric railways.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

FRUIT PICKER.—Amalea Fogeli of Nevada City, California, No. 452,102. Dated May 12, 1891. This device consists of a disk having a circle of upwardly extending pins about its periphery, the pins being separated and forming with the disk an open walled receptacle. A handle projects downwardly from the disk and is joined by a hinge, which is controlled by a latch. The picker is used by raising the disk up to the fruit, and passing any of its pins on each side of the fruit stem, the fruit itself resting on the disk. Then a slight turn or twist is given which breaks the stem, thus leaving the fruit uninjured in the receptacle. When full, the latch is operated and the jointed handle bends, whereby the receptacle may be turned to an angle to safely discharge its contents.

DOOR-MANIPULATORS.—Franz Schmitz of S. F., Cal. No. 452,084. Dated May 12, 1891. This invention belongs to the class of door openers and closers by which the door may be manipulated from a distance. It consists principally of a peculiar swiveled pulley secured to the door jamb for directing the cord which is attached to the door. The pulley turns to any angle to accommodate the different directions of the cord, according to the degree to which the door is opened, and it thereby prevents any cramping or hindering of cord. The device further consists in a single lever with suitable connections, for opening and closing the door.

Eastern Metal Markets.

By Telegraph. NEW YORK, May 21.—The following are the closing prices the past week: Silver to Silver in London. New York. Copper. Lead. Tin. Thursday..... 97 1/2 13 62 4 2 1/2 20 45 Friday..... 97 1/2 13 62 4 2 1/2 20 45 Saturday..... 97 1/2 13 60 4 2 1/2 20 45 Monday..... 97 1/2 13 50 4 2 1/2 20 45 Tuesday..... 97 1/2 13 50 4 2 1/2 20 45 Wednesday..... 97 1/2 13 50 4 2 1/2 20 45

Borax is weak under heavier supplies. Quicksilver is stronger. Tin is firmer. Lead is strongly held, but buyers are offish. Copper continues unsatisfactory.

PULVERIZER AND CONCENTRATOR.—Attention is called to the advertisement in another column of the "Common Sense Pulverizer and Concentrator." Mr. S. K. Snodgrass, the inventor, has had much practical experience as a miner and seems to have made liberal application of the principle as well as name by which his pulverizer is known. Many letters from those who have tested the machines by actual work bear ample testimony to the satisfaction it has given. Circulars and all particulars will be sent upon application to S. K. Snodgrass, 220 Sutter St., room 13, S. F.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irregular case, we shall be obliged to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

EASILY ACCOUNTED FOR.—If, as is alleged, the bar costs more in this country than our beef, and our tobacco more than our head, the destitution and suffering abroad are easily accounted for!

DELINQUENT SALE NOTICE.

GRAY EAGLE MINING COMPANY—Location of principal place of business, San Francisco, California. Location of works, Placer county, California. Notice—There are delinquent upon the following described stock, on account of Assessment (No 23) levied on the 31 day of April, 1891, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Shares.	Amount.

And in accordance with law, and an order of the Board of Directors, made on the 8d day of April, 1891, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 11, No. 308 California street, San Francisco, California, on TUESDAY, the 9th day of May, 1891, at the hour of one (1) o'clock P. M. of said day, pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

A. W. BARROWE, Secretary pro tem.

Office, Room 11, No. 308 California street, San Francisco, California.

VALVE AND PISTON ABEE.—To get the area of a valve or piston, multiply the square of the diameter by the decimal .7854.

NEXT to making a mistake yourself, the easiest thing is to criticize the mistakes of other people.

MINES and Stock in Mines for sale. See advertisement on page 321.

COMMON SENSE PULVERIZER AND CONCENTRATOR.

This is the most successful machine yet discovered for working Gravel, Cement, Clay, etc. It avoids crushing the rocks which are washed clean and at the same time pulverizes the Cement or Clay and SAVES EVEN FLOUR GOLD.

It is only necessary to have about six inches of water to work 100 tons or over per day.

Full particulars given by addressing:

VALLEY SPRING, CALAVERAS Co., CAL., July 19, 1890.

MR. S. K. SNODGRASS—Dear Sir: We find your machine perfectly reliable for four to five tons per hour, according to size of gravel. The work is well done, and not to exceed five per cent gets by, which I believe is very close work for any machine. Yours, L. A. SHEAD.

SAN FRANCISCO, March 25, 1891.
S. K. SNODGRASS, Esq.—Dear Sir: In regard to the work done by your machine, which we have had in operation for the past three months, I can say that it has handled successfully all material as taken out of our ground, the only cement which was not perfectly broken up being an exceedingly hard cemented material approaching rock in its hardness. For all free wash and moderately hard cement it will do very good work, and must effect a great saving in working such gravels and cements, owing to the small head of water required; and furthermore, its great gold-saving qualities, as I am satisfied that fully 95 to 98 per cent of the gold freed in the machine is saved, even to flour gold, and that too without the use of quicksilver. The automatic rejection of all rocks and material by the revolving screen makes the handling of the gravel cheaper, as all hand culling of the material is rendered unnecessary. Truly yours, W. W. B. STEVENS.

S. K. SNODGRASS, 220 Sutter Street, San Francisco.

Mining Share Market.

The week under review exhibited some of the old time life, with Con. Virginia the leader. This stock jumped from a little over \$16, closing on Wednesday to over \$20 the next day (Thursday), and on Monday afternoon sold as low as \$9.50 a share on Call, and \$9 after Call. The movements in this stock caused the remainder of the list to move in sympathy. The sharp up was brought about by sedulously circulated reports that the Jones (who are said to be insiders) had, after Samuel looked at the Con. Virginia mine, filled their shorts. This report and the sharp up had the desired effect of making nearly all outsiders who had shortened the market fill at a heavy loss, after which the pool sent prices down so fast as to swoop in big lines of stocks carried for outsiders by brokers. The only stop was when Con. Virginia touched \$14 at which figure the points were out to buy all along the line for something big. Large numbers acted on the advice and the something big was a big break, which broke about all who had put their heads in the lion's mouth by buying more than they could pay for. Brokers to protect themselves had to throw stock on the market without warning. This paper has repeatedly stated that when top prices were reached there would be a break of from 50 to 60 per cent. This was sufficient to keep many patrons from overbuying, and they made money by it. We will say now that the next break will be larger than the one just witnessed, but before it comes we are liable to have many setbacks. Insiders want certain stocks, and the stocks wanted they must have, and it is only by wide fluctuations they can get there. The mines are looking too well to let others reap the profits when they are compelled which will undoubtedly be done, to work the mines as required by the laws of this State, and when that time comes many dummy directors and officers will be made to disgorge, but it will be hard to reach those in the background and for whom the dummies work, but then those who rake nuts out of the fire for others to eat should be hurt.

In outside stocks the market has been dull at lower prices. The stocks are being concentrated for a bull campaign this summer.

From the Comstock mines our advices are of a still more encouraging character. Attention is being drawn by cappers and their friends to the 1100-foot level of Con. Virginia. The PRESS has said and will state again that it is not on that level the important work is being done; it is on the 1750-foot level. To reach the downward continuation of the very rich ore found on the 800-foot level, they will have to run on the 1100-foot level over 300 feet farther west from the point they are now reported to be at work. On the lower level (1750) the ore is rich, it is the same that was reported officially by Hon. James G. Fair, when superintendent of the mine. He gave its downward continuation from several levels above the 1750 foot. The ore has never been taken out. In Ophir they are pushing work to more fully develop the rich ore found to the west on the 1465-foot level. From Union and Sierra Nevada good reports can be expected any day. In the Middle group of mines the work is of a very important character. In the Gold Hill mines the dead work is about all over, although points are out that nothing can be expected from them until the water is pumped out, which evidently means until insiders get all the stock they want. Yellow Jacket is extracting gold-bearing quartz for reduction. Work in the Alta group is being favorably prosecuted.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Testing and Working Silver Ores

A VALUABLE BOOK.

An illustrated work of 114 pages, for miners and pro-
spectors, by Chas. H. Aaron. Mr. Aaron has managed
to give many useful hints and suggestions, free from
all technicalities, and in such a style as to be easily
comprehended. It is written for the miner, with no
chemical symbols or metallurgical technicalities to con-
fuse those who are not chemists or metallurgists. The
following summary of the contents of the work will give
an idea of its scope.

Under the heading of the first chapter, "Testing Ores
for Silver," we find paragraphs on ore formation, test for
silver, with heat and water, acid or blow pipes. In speak-
ing of testing for a process, the extent and richness of
ore is considered, smelting, ores, selecting and working
samples, appliances for testing, roasting, etc. Under the
head of "Working Ores" the author describes Aaron's
process, has something to say of superheated steam, pre-
paration of dichloride of copper and protochloride of cop-
per, use of copper and iron, quantity of chemicals, car-
bonate of lime, chloride ores, amalgam, Pathe's pro-
cess, etc. He also describes the methods of working
roasted ores, treatment of base metals, stirring, heat of
furnace, want of sulphur, etc. Under the head of
"Leaching Processes" are the titles Smelting, Mexican
process, Chilean process, Kroehnke's process, etc. Under
"Pulverizing Machines" are described the arastra and its
construction and operation, stamp batteries, sereas,
Orocker's trip-hammer battery, Paul's pulverizing barrel,
Kendall's battery, Noice's pulverizer, a cheap rock
breaker, etc.

In speaking of amalgamators the author describes a
cheap amalgamator, grinding the ore, directions for mak-
ing a barrel, preventing mechanical wear, use of quick-
silver, copper in bars, Freiberg barrel, cheap barrel
trough, barrel on rollers, Aaron's amalgamator, separa-
tor, etc.

He describes an improvised retort, roasting furnace,
furnace tools and furnace building. Among the miscel-
laneous mention may be found Aaron's leaching apparatus,
with two or three different arrangements, a small mill,
sampling tailings, and settling tanks, dichloride of cop-
per, etc. Mr. Aaron is a practical miner, of long working
experience on this coast.

Price, post free, \$2.00. Sold by Dewey & Co., Publish-
ers, 220 Market St.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the
"Explorers', Miners', and Metal-
lurgists' Companion."

A practical exposition of the various departments of
Geology, Exploration, Mining, Engineering, Assaying,
and Metallurgy.

Price, \$3.00 post-paid. Sold by Dewey & Co., Publish-
ers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins,
Testing and Assaying. The geological chapters are in-
tended to give miners a practical idea of the various
formations. The chapters on mineral veins are derived
from long observation, and the section on exploration
has been carefully considered. All that relates to dis-
crimination and assay of minerals has been kept as free
from ornate as possible. The work is written for
practical men, and all the explanations and descriptions
are clear and to the point. It is so prepared that it is
useful to uneducated men as well as scientists.

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.

121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS.

Varying from the fraction of 1 up to 15 and 20-horse power, unequaled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

VOL. LXII.—Number 22.
DEWEY & CO., PUBLISHERS.

SAN FRANCISCO, SATURDAY, MAY 30, 1891.

Three Dollars per Annum.
SINGLE COPIES, 10 CENTS.

The Tierra Seca Gold-Extracting Machines.

The numerous localities in different parts of the world, where the necessary supply of water is not obtainable, or at best, intermittent, has led to many inventions, looking not only to the dry washing of gold, but to the separation of other metals from their matrix. Fig. 1 represents a dry prospecting machine, which can be made to weigh only six pounds, while Fig. 2 represents a dry concentrator, built in two sizes, weighing 350 and 600 pounds, respectively. They are the invention of Mr. Chas. Wetziar, and have attracted considerable attention. The bed of machine represented in Fig. 1 has a series of bars one-sixteenth inch in diameter, laid transversely to its length, the bars making a riffle three-fourths inch wide at the top, the others being placed one-half inch apart to the bottom end of the bed, forming a series of riffles.

The bed fits into an inclined groove, on each side of machine, the top end coming directly under the hopper *c*; the frame is made air tight except through the gauge forming the bottom of machine. The sides of the feed hoppers are formed by the sides of fan *a*, the body of which forms the back end, while the front end is a

movable sheet of iron, which slides in grooves out in the side, regulating the size of the opening on to the ore bed, according to the material to be treated. The powdered material is fed into the boppers, the fan started, and the feed opened to the required extent. As the material traverses the ore bed the light particles float away, leaving the metal on the bed.

Dry Concentrator.

The dry concentrator shown by Fig. 2 uses the method of introducing the material to be concentrated into a box, through which flows an intermittent current of air. This rising through a sieve in motion, sustaining a layer of shot, carries away the lighter gangue, the heavier particles, falling by gravity among the shot, sink through a sieve into a suitable discharge.

As will be noted there are seven parts to the machine: The feed hopper 1; the shot box 2; the main shaft 3; the Archimedeian screw for ejecting tailings 4; the exhaust fan 5; the exhaust regulating tappet valve 6; and the exhaust regulating slides 7.

Attached to the main shaft, there is a belt pulley to drive pulley of the fan; also a belt for driving the spindle of the tappet for the regulating tappet valve, and a step cone pulley for driving the Archimedeian screw at varying speeds. The No. 1 machine is said to require but $\frac{1}{2}$ of 1

Timber Block for Brake

BRAKE USED IN DEEP MINING.

horse-power to drive it, and to have a working capacity per day of from four to seven tons. The No. 2 machine requires $\frac{3}{4}$ of 1 horse-driving power, and has a capacity of 20 to 30 tons per day.

Burns' Brake.

Connected with haulage in deep mines, the importance of having efficient brake power is indisputable, particularly where winding is done with a single rope. In the one presented on this page, we show an invention, patented by Mr. T. Burns, engineer at the Bickenshaw collieries. Mr. Burns contends that with his brake, there is less first cost, and less cost in working than with the ordinary foot brake and steam brake with straps passing at least half around the drum ring.

He uses no steam, the brake being worked without any undue exertion by the engineer, and is so constructed that either an enormous

force, or a very slight one can be put on without any sudden jerk.

It is claimed that these brakes will easily give a leverage of 200 to 1, affording a retard-log force of five tons, and that a separate brake can be attached to each brake ring, thus multiplying the power to any extent. By means of adjusting screws, the brake can be tightened or slackened by the engineer in a few seconds, without leaving the engine-house, the handles being adapted to any position desired.

The new railroad to Anaconda will be three and one-half miles shorter than the old one. The Butte depot will be within three minutes walk from the courthouse, and the Anaconda depot at the head of Main street in that city. The connection with the mines of the company will be easy, the question of grades having been rendered simple by the enormous power of the engines now available for such work.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—Eds.

Notes From Sonora Mexico.

EDITOR PRESS:—The St. Helena gold mine at Las Delicias on the Sonora river is now running its business steadily, its 60-stamp mill is being constantly in operation running partly on tailings of which many thousands tons are banked from former years, and partly on ore extracted from the mine. The tank process is being used, the Boss continuous having been discarded. It is pleasant to know that this business so important to this part of Sonora is once more in activity after so many shut-downs for one cause or another. Capt. L. W. Mix formerly of San Francisco is the General Manager, and a large force of American mechanics and Mexican laborers is employed constantly. A new electric light plant was inaugurated on the beginning of last week, and as I understand successfully.

Messrs. Magruder & Fresh, who have been long identified with mining interest in this State, have lately commenced at a place commonly known as the Carbonera, the running of a 5-stamp mill on gold ore extracted from a mine near by. This mill is an old one and was erected by Tucker & Hardwick several years ago, but proved unsuccessful because they were unable to treat the ore. The mill having been reconstructed and new machinery added the above trouble has been obviated. In place of amalgamating in the battery and on plates a Cook Amalgamator is now being used and with good results. Mr. Fresh is in charge of the business, and Mr. Magruder continues to operate the Yeco mines and mill at Las Cruces. The Gavilan mines which at one time were supposed to be sold to an English syndicate for £40,000 were not disposed of, owing to some hitch in the negotiations with Mr. Martin. These mines have since been examined by an Eastern expert in the interest of Boston people, and a very favorable report made thereon if rumor can be believed. The owners confidently expect that the business may start up with capital sufficient to make a success of the property.

There has been a large influx of natives into the "Oro Negro" camp from the surrounding country, owing to the fact of the great activity of the above company. Their mines are rich, and as they have worlds of ore in sight, are being operated very successfully.

A late letter from the camp at the Sierra de Lopez, the location of the Popocatepetl mine, owned by Don Rafael Fort & Co., says that their stamp-mill is nearly ready for starting, and the property is looking splendidly. A great success is anticipated for the enterprise.

At Minas Prietas, the old mill, I believe, is running steadily on tailings. Price's mill is running days only, the water supply being short. He is making strenuous efforts to increase the supply, from a spring named "El Chivato."

The placers near Fronteras, to which many hurried some months ago, have, like many such schemes, had their boom, and are now having their collapse. It has been a case of "much cry and little wool." That there is gold in small quantities in the district, near Bacochi and Fronteras, is evidenced by the amount of work done by the "Antignos." I have seen hesitating nuggets from near the former place.

Mining business just now is looking up here, and several parties are seeking after good properties. Mr. Jeff Bickerton, from the Tohachi mine near Campas, is making regular shipments of rich ore to the United States, and is doing fairly well, although freight to Sonora R. R. costs him very heavily, owing to the great distance he has to transport his metal.

It is said that the city of Ures is to be lighted by electricity shortly, through the public spirit of that friend to Americans in his vicinity, Don Francisco C. Aguilera, ex-Prefect of the Ures district.

The skies are clouding up this summer, and it looks as though rains would be early. Yesterday there was some thunder, and on May 4th a slight earthquake shock was experienced, reminding one of the 3d of May four years ago, when the earth trembled perceptibly and soared many. Flour has been extremely high here lately, but now a new crop of wheat is about being harvested, insuring a fall in prices.

"AMERICANO."

Hermosillo, May 10, 1891.

Letter from Arizona.

EDITORS PRESS:—I had calculated to send you another communication from Oro Blanco district before now, but owing to circumstances over which I had no control I have been prevented doing so. However, I proceed to describe the workings on the different claims lying easterly from the Yellow Jacket lode and mine.

The Border mine, which has a number of shafts and tunnels of short lengths and depths, shows good ore everywhere. The main, or new shaft, now down some 30 feet, shows a ledge the full width of the shaft and no walls. There are now 20 tons of ore on the dump awaiting shipment by burro train to the Con. Arizona mill. This is termed second-class ore, the first-class being sold to Salazar, the pre-

mier at Nogales. I learn from good authority that the last-named ore produces from 100 to 200 ounces silver per ton, while the second grade may run from 75 to 80. Four men are working in this mine and development work is progressing proportionately.

Since my former article a large body of high-grade ore has been discovered in the Montana mine, and the party, J. W. Bogan & Co., who hold a two-years' lease thereon, are elated over the fact, as they have in the Montana a veritable bonanza.

The main tunnel is now in 300 feet or more and onto the mountain at this point 130 feet below the surface.

Several crosscuts show at different places in this tunnel a body of ore 30 feet wide. The higher grade of this ore is soaked and shipped to El Paso yielding, I am informed, an average of 60 ounces silver and 40 per cent lead per ton. Of this class there are several feet and the lower grade is first concentrated at the Con. Arizona mill and then shipped to El Paso. There are employed here eight or ten men in the mine, and a number outside filling sacks and loading wagons. A new wagon-road has been built to the mine giving the company cheaper transportation for their ore and more rest to the former heavy-laden burros.

The Peeltick, Manyana, China mine and several other locations on this lode near the Montana are promising-looking claims, but as yet show no development work of importance, simply for want of the necessary capital to do so.

The Austertiltz contains three shafts—one 60 feet one 40 and one 30 feet deep. The 60-foot or main shaft has a drift along the ledge 40 feet in length, at the end of which there is a crosscut showing over five feet of gold ore, yielding \$15 per ton by mill test. The upper or 40 foot shaft shows 2½ feet ore, averaging in gold \$25 per ton. Shaft No. 3, same size and same grade of ore as the 40-foot shaft. Ore from the drift along the ledge at bottom of mountain, 25 feet in length, assays from \$20 to \$60 per ton in gold, with a few ounces in silver. The average mill test of the 400 tons taken from the various workings on this claim was: Gold, \$14; silver 12 ounces per ton. The Forsaken, Continuation and a few other locations in the vicinity of the above mine cover large surface deposits; not sufficiently worked, however, to tell much of their probable worth.

The Ragnarok is virtually a mountain of ore, the lode here carrying more silver than gold. Several openings in various parts of this claim show ore everywhere, and although 150 tons have been taken out for milling purposes, hundreds of tons yet remain on the dumps, there being thousands of tons left in sight. The same story, as regards development, can here be told, viz.: Cash to work it.

But one may say, with so much ore easily gotten out, why not quarry it out and have it milled? In reply, I give the reason as above. There is but one 10-stamp mill in operation (excepting the Yellow Jacket of 20 stamps) in these parts, and they hold to a milling price of \$22 per ton for milling the ore, and guarantee no account of battery samples, and this, together with say \$3 per ton for packing to mill, leaves no return for the miner.

There is no doubt but this ore will average \$30 per ton, it being the most free milling of all ores in Oro Blanco district. Yet even should the mill-owner guarantee 80 per cent of this, with the enormous price charged for milling and a few dollars per ton for packing, it would not leave him enough to pay the Mexican miners \$1 a day for taking out the ore.

A number of other locations having claims between the above mine and the Ostrich are complaining of financial starvation. The Yellow Jacket, after suffering from the same cause for long years, shows a prosperous condition. The 20-stamp mill is in constant operation, and the ore body of sufficient size to require only eight miners to keep it supplied with ore.

Oro Blanco, May 13, 1890. I. C. U.

"Loss of Gold."

EDITORS PRESS:—On returning to this city, my attention was called to an article in the *Miner*, published at Nelson, B. C., and headed "The Best Method to Treat Gold Ores," which article is signed "James Dalevan."

This article, like for line (except the title) was written by me and published in the MINING AND SCIENTIFIC PRESS of April 11, '91, under the heading of "Loss of Gold—Practical Tests in Milling the Gold-Bearing Rocks." It is incredible to think that any piece of humanity making the least pretense to respectability, would, (unless there is some onerous mistake) so unblushingly put before the public another's work as his own.

Stealing literary labor is considered an unpardonable act, but how much baser is it when one appropriates the results of manual labor, and moneyed expenses with it.

The tests described in my article cost over \$500 to make, and I gave them to the public for their benefit. It is very strange that any one would be wilfully guilty of such an act as the one above referred to.

ALMARIN B. PAUL.

San Francisco May, 10, '91.

EXPANSION AND CONTRACTION OF STEEL RAILS.—A roadmaster in *Railway Age*, says that steel rails expand or contract one part in each 148,000 parts with each degree of change

in temperature. The Pennsylvania railroad tracks from New York city to Pittsburgh are 353 miles in length, and in the distance the expansion of the rails will amount to 12 feet 6 inches for every degree of change in temperature. Between the 90° weather of August and the zero temperature of mid-winter, the tracks shrink 1134 feet, or more than one-fifth of a mile.

English Mine Statistics for 1890.

The statistics of the mines of the United Kingdom together with the Isle of Man for the year 1890, have been published, and of them the *Iron and Coal Trades Review* presents the following summary:

During the year the total number of persons employed in and about all mines in the United Kingdom, together with the Isle of Man, and inclusive of those employed on private branch railways and tramways, and in washing and coking coal on premises adjacent to or belonging to the mines, amounted to 674,434, of whom 5390 were females above ground. The number employed in and about all the mines, exclusive of all those employed in these ways, was 655,287, of whom 5599 were females, the aggregate increase being 48,132. The total number of fatal accidents was 899, and the total number of deaths occasioned thereby 1206, being a decrease of 13 in the number of fatal accidents, and an increase of 73 in the number of lives lost, compared with the totals of the preceding year; there was one death for 543 persons employed, which is more favorable than the ratio, one in 538, of the preceding year.

The total number of persons employed in and about the mines under the Coal Mines Regulation Act was 613,233, of whom 4206 were females working above ground, the aggregate increase being 49,498, compared with the preceding year. There were 861 fatal accidents and 1160 deaths, the number of accidents being 13 more than the preceding year, and the number of deaths being 96 more. There was one fatal accident for every 712 persons employed, and one death for every 528 persons employed. The accident ratio is more favorable, but the death ratio slightly less so than in the preceding year.

The total quantity of mineral wrought in the different districts was 194,605,887 tons, of which 181,614,288 were coal and 3,117,476 ironstone, the rest being fire-clay, oil shale, and other minerals, making a total increase of 4,972,231 tons compared with the preceding year. There was an increase of 4,697,564 tons of coal, but a decrease of 153,066 tons of ironstone. The ratios of the fatal accidents and the deaths to the number of persons employed in and about mines under the present and former Coal Mines Act are given in averages for the periods covered by the first three acts and in detail with averages since 1872. From these it appears that the occupation of the miner is now more than twice as safe as it was at the commencement of the Mining Acts, the average ratio under the first act being one death in every 233 persons employed, under the second act one death in 258, under the third act one death in 312, under the fourth act one death in 496, while for the last year it is one in 528—a much more favorable ratio.

A table of the hours of the deceased persons' shifts in which the fatal accidents happened shows that in only five cases had those to whom the accidents occurred worked more than 12 hours overtime.

The number of persons employed on private branch railways and tramways, and in washing and coking coal on premises adjacent to or belonging to the mines, was 19,147, of whom 291 were females; the number of fatal accidents was 33, and the number of deaths resulting therefrom was 34. There was one fatal accident for every 580, and one death for every 563 persons employed, which are more favorable ratios than in the preceding year.

The output of coal last year shows an increase of nearly 53 million tons over that of 1873.

The total number of persons employed under the Metalliferous Mines Regulation Act was 42,054, of whom 1393 were females employed above ground. There were 38 fatal accidents and 46 deaths, the number of accidents being 26 less and the number of deaths 18 less than in the preceding year. There was one fatal accident for every 1106 persons employed, which are more favorable ratios than in any preceding year.

Need of Ventilation in Cars.

Considering the importance of ventilation in cars, and how much has been said and written about it, it seems remarkable that so little has been accomplished to improve it. When persons fall into error, it is because they either believe something which is not true, or do not believe something which is true. Now, in our ventilation, the true thing that is not believed is the absolute need of furnishing an adequate supply of fresh air to keep the atmosphere in a car pure.

The average car-builder and architect will always assume that by simply making a number of holes in the top of a car or apartment, that the bad air will escape, but he never seems to inquire how the fresh air, which must take its place, will get in. We remember once seeing the principle of ventilation illustrated very forcibly in a car shop. It was found that newly varnished blinds for car windows would not

dry unless a certain amount of warmth was applied. A close apartment or drying-chamber was then constructed, which was warmed with steam pipes. In it the drying proceeded to a certain extent and then stopped. Investigation showed that the air in the chamber absorbed a certain quantity of the volatile constituents of the varnish, but would take up no more than a given amount. If the air which was thus charged was removed, and a fresh supply was furnished, the drying continued, which led to a system of ventilation by a fan, which forced air into the chamber, and that which had absorbed some of the component parts of the varnish escaped through suitable openings. Simply adding ventilators for the escape of vitiated air was not sufficient. A constant and certain quantity of that which was fresh had to be admitted to the drying-chamber. The same principle applies to car ventilation. There must be an adequate supply of fresh air to keep the atmosphere in the car pure. Such a supply is not ordinarily furnished on the vestibule trains.—*Railroad and Engineering Journal*.

The best ventilated car we ever rode in was one on the Connecticut River R. R. some years ago. This was a smoking-car, and between each seat was a round six-inch hole clear through the bottom. This let the foul air out, and the fresh air came in at the top. This car was always clear of smoke, and it was warm, too. The principle was correct.—*The Engineer, N. Y. City*.

The Big Things of This World.

The largest suspension bridge in the world is the one between Brooklyn and New York. The length of the main span is 1595 feet 6 inches. The entire length of the bridge is 5989 feet. Fortress Monroe is the largest single fortification in the world. It has already cost the American Government over \$3,000,000. The water battery is considered one of the finest military works in the world. The loftiest active volcano is Popocatepetl (smoking mountain), 35 miles southwest of Puebla, Mexico. It is 17,734 feet above the sea level and has a crater three miles in circumference and 1000 feet deep. The largest university is that of Oxford, England. It consists of 25 colleges and five halls. The most extensive park is Deer Park, in the environs of Copenhagen, Denmark. The inclosure contains 4200 acres and is divided by a small river. The largest pleasure ground in America is Fairmount Park, Philadelphia, which contains 3740 acres. The largest body of fresh water on the globe is Lake Superior. It is 400 miles long, 160 miles wide at its greatest breadth, and has an area of 32,000 square miles. Its mean depth is said to be 200 feet and its greatest depth about 900 fathoms. Its surface is 635 feet above the sea. The largest tunnel in the world is that of St. Gothard, on the line of railroad between Lucerne and Milan. The summit of the tunnel is 990 feet beneath the surface at Andermatt, and 6600 feet beneath the peak of Kasselhorn of the St. Gothard group. The most extensive cavern is the Mammoth Cave, in Edmonson county, Kentucky. It is near Green river, six miles from Cave City and 28 miles from Bowling Green. The largest trees are the mammoth trees of California. One of a grove in Tulare county, according to measurements made by members of the State Geological Survey, was shown to be 276 feet high, 105 feet in circumference at the base, and 76 feet at a point 12 feet above the ground. Some of the trees are 376 feet high and 34 feet in diameter. Some of the largest that have been felled indicate an age from 2000 to 2500 years. The largest island sea is the Caspian, lying between Europe and Asia. Its greatest length is 760 miles, its greatest breadth 270 miles, and its area 18,000 square miles. The largest empire in the world is that of Great Britain, comprising 8,557,658 square miles (more than a sixth part of the land of the globe), and embracing under its rule nearly a sixth part of the population of the world. In territorial extent the United States ranks third, containing 3,580,242 square miles, including Alaska; in population it ranks fourth, with its 60,000,000 people. Russia ranks second, 8,352,940 square miles. The highest monolith is the obelisk at Karnak, Egypt. Karnak is on the east side of the Nile, near Luxor, and occupies part of the site of ancient Thebes. Its whole length is 122 feet, its weight 400 tons. Its height, without pedestal, is 180 feet 10 inches. The Chinese wall is the longest wall in the world. It was built by the first Emperor of the Tsin dynasty, about 220 B. C., as a protection against Tartars. Its length is 1250 miles. Including a parapet of five feet, the total height of the wall is 20 feet, thickness at the base 25 feet, and at the top 15 feet. The largest library is the Bibliothéque National in Paris, founded by Louis XIV. It contains 1,400,000 volumes, 300,000 pamphlets, 175,000 manuscripts, 300,000 maps and charts, 150,000 coins and medals. The collection of engravings exceeds 1,300,000, contained in some 10,000 volumes. The largest hell in the world is the great hell of Moscow, at the foot of the Kremlin. Its circumference at the bottom is nearly 63 feet, and its height 21 feet. Its weight has been computed to be 443,772 pounds.—*Machinery Market*.

JUDGE—"Prisoner, are you married?" Prisoner—"No, yer Honor; those scratches on my face came from stumbling over a barbed wire fence in the dark."

Equitable Protection to the Brain-Workers.

The sessions of the "Patent Congress" at Washington have attracted attention anew to an old subject and revived the familiar and ridiculous criticism that our patent laws serve to promote monopoly.

The American patent system simply aims to secure to one sort of property the protection which the laws of all countries afford to other kinds. A man's house or his horse is his own to hold for proper use against all the world, and all the rents or earnings are his by universally recognized rights. Yet a man's house or horse is no more his own than is his thought, but rather less; and why should not his mental possession be guaranteed to him as well as his material property?

It is to guard this right of the idea during the process of actualization so that it can be seen, felt and made useful and enjoyable that our patent laws exist. They are not in their nature monopolistic, but the reverse, for their is nothing more opposed to monopoly than the free development of practical individual thought. The function of the inventor is to innovate, to break in upon some long-established method, of substituting a new and better one for it. Its tendency is to prevent monopolies from becoming inveterate, and indeed, to cut the very ground from under their feet. If established monopolies could have their way they would stop invention except by their own employees, and some of our monopolistic corporations have devoted so much energy to this end that they have been serious obstacles to the progress of American inventive science.

The operation of the patent laws is not one-sided. The discoverer of a novel and valuable apparatus or process surrenders to the world at large his secret, which is often the only product of a lifetime of wearying thought and unremitting industry. In return the country simply guarantees to him opportunity for income from his own creation during a short term of years. The world is the gainer in the advance of prosperity, comfort and intelligence. The inventor's gain, even in the rare cases in which it proves really remunerative, is but trifling compared with that derived from his thought and labors by his fellow-men. Ordinarily invention does not pay. Some of the most notable inventive achievements of the age have left their creators impoverished. It is the instinct and faculty of creating, which in literature is called the poetic faculty, that in mechanic arts and material science becomes invention. It is the natural field of bright and practical minds, of intellect of the sort upon which freedom and progress depend. There is nothing in all our institutions more truly or more happily American than the patent system of the United States.

It is to our patent laws as much as to any other cause that our country owes its prosperity and its prominence in the world. The patent system is one to be guarded with the utmost care and preserved in its vigor and purity against all corruption and abuse. Sincerely, competently and purely administered, it will continue to be one of the most interesting and beneficial features of our Government.

Silver at Butte.

The fact that this is the greatest copper producing camp in the world is apt to obscure in many minds the importance of the silver interests here. The mines from which the white metal is produced would be the first in any other camp of the world, and are only overshadowed here, as is the rest of the metal producing world, by the wonderful copper properties that have made Butte the admiration and envy of all its competitors.

In a general way the silver belt lies west and north of the city with the copper on the east. The two belts, however, merge into each other, and the ground between bears both metals. A queer instance of this is to be found in the Gray Rock, which is about on the boundary line north between the two. Here the ore bodies are found in chutes, one of which will be chiefly valuable for silver, while perhaps the next will be rich in copper. North of this point are found many of the most valuable among the silver mines of the state. It is the opinion of a great many of the best posted miners in the camp that as soon as these mines have been sunk to a sufficient depth their ore will all be found to be copper. This is the case with the Park Canyon mines, where the rock here silver on the surface and is chiefly valuable for copper now that some depth has been attained. The same was found to be true of a number of the mines on this side of the valley, which are now noted for their output of copper. This, should it prove to be the truth, would not detract from the value of the properties in the least, and in fact the same authorities declare they would be even more valuable.—*Inter-Mountain.*

RUSSIAN MINES.—A few days ago 300 pounds, or 10,800 solid pounds of gold (one good Russian equals 36 pounds English), were received at the mint in St. Petersburg from the Crown mines, in the district of Irkutsk. In the last 50 years about 60,000 pounds, or 2,160,000 pounds of gold (English weight), have been obtained from the gold washings of Eastern Siberia alone. Silver, lead, copper, etc., are

found in still greater quantities in Siberia, and when the trans-Siberian railway is constructed the yield of the precious metals will most probably be double what it is at present. The coal and naphtha beds of Russia are another source of future wealth to that country. Out of a single spring in the vicinity of Baku, Messrs. Noble Brothers obtained during the past year 25,000,000 pounds of naphtha, which represents a cash profit of 1,500,000 roubles, after paying 100,000 roubles for the rent of the ground on which the spring was tapped. This spring is now still giving about £50 worth of naphtha a day. The vast coal beds of Russia have still to be exploited.

What We Owe to the Invention of Machinery.

Few persons have any correct idea of the difficulties which were met with 60 to 70 years ago in making suitable tools and machinery from metal. There were no planing, boring or shaping machines; the turning lathe and the drill-borer were about all the devices which could be called into use by the mechanic of that time. Inventors had to make by hand the machines they invented, with the aid of other machines in making the individual parts. They had to invent some tools so as to be able to make certain parts of their invented machine. When the celebrated English machinist Clement entered a shop as master at London in 1814, he found the tools so poor and defective that he had to spend days in making such ones as were needed. James Watts, the inventor of the steam engine, could not get his first machines in working order in consequence of a lack of some contrivances. The first cylinder which he had cast was not tight, and was on one end five millimeters wider than on the other. A good cylinder should not show more difference in width than one-half millimeter.

And then the cost of work at that time was extravagant. Whitworth, one of the oldest manufacturers of working machines in England says that the polishing of cast-iron cost \$3 per square foot 40 years ago, as the work had to be done by hand. The manufacturer Perry paid for the first steel pens \$1.25 a piece, but still these pens were not as good in quality as those which are made to-day. After factories had been established, the price of a steel pen was still \$1, then 50 cents, and then 25 cents, which price was kept up for some time. To-day one can get a gross for that price; all owing to our perfect machinery.

Chicago's Leaning Tower.

As one of the attractions of the World's Fair, Chicago proposes to construct the greatest leaning structure in the world.

This engineering novelty is a massive tower, having an elevation of 225 feet, about 70 feet square, and boldly leaning 100 feet from the perpendicular. The entire structure is of metal, principally steel, weighing about 500 tons above the foundation, and of novel cantilever construction that affords all requirements of stability. It will be built to safely sustain a load of 160,000 pounds on the floor of the top story.

The framework is of steel truss construction, forming a huge cantilever of enormous strength and rigidity, which combines for support a sub-structure of metal. The depth of sub-structure is 45 feet, area 165x115 feet. The construction of the foundation is chiefly of plate-riveted iron girder work imbedded in concrete, which forms a solid bed about 18 feet deep. This girder-concrete foundation has the characteristic of being continuous in structure and rigid throughout, and is especially designed for building on yielding substrata, such as the deep clay of Chicago. On the girder work, there are bolted steel bearing plates, and on these plates the massive truss-foot of the cantilever rests. This foot at the left side will be attached to metal parts of the bed by large steel pins and eye-bars, but these connections will not be brought into play unless the tower is heavily loaded.

In the superstructure, three lines of trusses constitute the main supports, two, forming sides of the tower, the third has a middle position, and a lateral truss system braces them together. Pin connections are used for truss members. The walls of the tower are comparatively light, being simply a framing of small-sized angle iron attached to the truss work, and having a facing of embossed sheet metal. The exterior will be painted a dark terra-cotta color.

Electric hoist elevators and easy stairways conveniently lead from entrances to the upper stories. Above the first story, there are five floors. They are inclined, and consist of a series of broad steps extending across the tower. Numerous windows light the interior, balconies provide interesting outlooks for visitors, and at the top of the tower an extensive view of the surrounding city and a mid-air realization may be had. A delicious buffet serving light refreshments will be in the top story, and about midway will be the tower observatory shop. The visitor can also reach the foundation and view its construction.

The structure is designed by J. B. Halpinny, architect, who says it will take eight months to complete the work, including the shop work and erection. The cost will be about half a million dollars.

The Truth About Aluminum.

Despite the emphatic denial recently published that there was any need of lowering the price of aluminum below \$2, owing to the demand for it at that price exceeding the present supply, it appears that it is now being offered to the trade by one of the manufacturers at from \$1.25 to \$1.75 per pound, according to the quantity, says a writer in *Fire and Water*. There has been a great deal of exaggerated nonsense written about this metal and the use to which it is adapted, and to which, in time, we may expect to see it put, as, for instance, in the construction of ships and bridges, in place of iron and steel. It possesses, however, undeniably valuable qualities, and as the methods of producing it are perfected and the cost still further reduced, it is likely to be utilized to advantage in the stead of silver, German silver, copper, tin and zinc for a number of the purposes for which these are used.

The most valuable qualities of aluminum, as enumerated by a recent authority upon the subject, are its ductility under drawing processes and its non-liability to corrosion. It can be rolled into sheets .0007 inch in thickness, beaten into leaf, drawn into tubes and spun or stamped into various shapes. It is susceptible of a high degree of finish by polishing or burnishing. It becomes hard by working, and requires frequent annealing. It melts perfectly fluid at about 1300° but becomes granular at about 1000° F. It is most easily worked at a temperature of from 200° to 300°. It is apt to become granular and to stick to the rolls at a higher temperature.

As to the corrodibility of the metal, it is unaffected by either dry or moist air, by water, by sulphuretted hydrogen or other sulphur vapors, by salt sea water, a weak solution of salt in acetic acid or by sulphuric or nitric acids. These acids, however, rapidly act upon the metal in the presence of chlorine. It will be readily understood, then, that even if some of the extreme claims made for it are unfounded, its cheap production will prove of great advantage to many different industries.

Domestic Tinplates.

A recent announcement was to the effect that an important establishment had resolved to abandon the erection of a contemplated galvanized sheet works, and to devote whatever capital and energy might have been required in that direction to the manufacture of tinplate. The admitted reason for this change of purpose was, that under existing trade conditions the manufacture of tinplate held out more inducements than the manufacture of galvanized sheets. It must be confessed however, that progress in domestic tinplate making has not been so rapid as many people hoped that it would be. Tinplate andterne plate are being made at several works, it is true, and preparations are going on looking to the erection of other plants, but there is a conservatism, a deliberation, about the whole proceeding which is decidedly at variance with the activity promised by the advocates of a tinplate industry. It had been supposed that a large number, if not a majority, of the sheet mills would add cold rolls and tinning stacks as soon as an adequate tariff protection was assured.

It has been urged that if there is ever to be a time when the manufacture of tinplate will be taken up by the sheet men generally they could hardly find the conditions more favorable than they are at present. While, of course, all the sheet mills in the country are not adapted to rolling sheet for tinplate, a number of them unquestionably are. We are informed that the assurance of a regular supply of black sheets at a suitable price is all that is needed to lead capitalists to embark in putting up the efficient number of tinning stacks.—*Metal Worker.*

IRON IN WASHINGTON.—The Edinburgh *Capital* says: It is an established fact that as fine a quality of pig iron can be made from the iron ore found in this vicinity as is made any place in the United States. Our mountains are full of the ore, fluxing and fuel are to be had in abundance, and there is only one thing in the way of producing pig iron and even steel rails and other products of the mill. We are experiencing just what every new country goes through—that is lack of capital. We know just what can be done here, for in a small way it has been demonstrated that our ore is easily and cheaply worked; the market is waiting for our product, but we have not heretofore produced it. Nothing now stands in the way of this desirable result but money, and while a large sum is needed to establish immense works, a comparatively small amount would put fire in the furnaces and enable us to produce enough pig iron to give us a favorable introduction to the market. This done, we would consider the battle won and our iron industry would be on its feet to stay. The day is not far off when our reconnores in this line will be fully appreciated, and then capital will be glad to come to us. It cannot afford to ignore the riches that lie here ready to be turned into money, and when the present financial stringency has passed away there will be an awakening here such as no one now dreams of and Edinburgh will take her place as the iron city of Washington and hold it against all comers.

Buried Trees in Gravel Mines.

In the gravel deposits of the ancient river-beds of the Forest Hill Divide in this State, trunks of trees similar in appearance to our present oaks and oaks are found imbedded in the upper layers, either petrified or somewhat lignitized. Mr. Ross E. Browne, in a chapter of the *Mineralogist's* report on ancient river-beds, calls attention to an interesting occurrence in the Weske channel. The cement filling the bed to a depth of 100 feet is a more uniformly fine-grained sediment than is commonly encountered. It incloses a number of oak and cedar trees, standing on the banks of the channel, with the roots intact in the gravelly soil and bedrock. One of these is a cedar nearly 100 feet in height and 4 feet in diameter at the base, and stands perfectly upright, and, considering its age, is in a surprising state of preservation.

Similar standing trees are also found in the Bowen mine, in the same channel. These trees are immediately on the shore line of the shallow deposit of gravel, and show that for a few centuries at least before, the depositing of the volcanic material was a small one.

These standing trees show also that the first flow of the auriferous cement was not torrential, though moving with a certain velocity. The existence of a current, and its direction, are plainly indicated by the structure of the deposit immediately surrounding the trunks of the trees. The deposit where these standing trees are found is entirely covered with an extensive and deep cap of lava.

Coal Dust a Cause of Explosions.

It having long been suspected that coal dust in mines, becoming ignited by powder blasts, were the cause of violent explosions, the following remarks of the Hon. H. Mathews, Secretary of State, Province of Nova Scotia, will be read with interest, these remarks being addressed to the Inspector of Coal Mines:

"My attention has for some time been directed to the effect which the presence of coal dust in mines may have in originating or in propagating explosions. Two disastrous explosions have occurred in the course of the present year at the Ilanerob Colliery and the Morfa Colliery. Both of these explosions were made the subject of careful investigation by competent men.

"The conclusion deduced by Mr. Hall from experiments is that a blow-out shot may in the presence of coal dust, and in the entire absence of fire-damp, cause explosions of great violence, often accompanied by volumes of rushing flame, traveling considerable distances, and possibly so far as the supply of coal dust continues.

"I strongly urge upon colliery managers that in all mines of at all a dry and dusty character the accumulation of dry coal dust should be prevented by removing the dust and watering work-places and roadways (roof and sides as well as floor), and further, that shot-firing with gunpowder should only take place when all the workmen have been withdrawn from the seam."

QUARTZ AND GRAVEL AT TRUCKEE.—Mr.

McGlashan in running a tunnel for water in the side hill just above and west of Mrs. Cassidy's, has struck a bed of gravel that has every appearance of having once been the bed of a large stream. The gravel is coarse and washed smooth. Jack Williams prospected a shovelful of it and succeeded in getting several ounces of gold. The cut and tunnel is now in about 50 feet. Bedrock has not yet been reached and the width of the channel is not known. It is possible that pay gravel will be found next to the bedrock. Somehow no one ever thinks of this part of the country as containing any valuable deposits of gold. It's too high up, the experts say, and there is too much granite in the country. But experts don't know everything. The fact of the matter is, this section has never been prospected. To be sure there were two or three mining excitements in this neighborhood in the early sixties, but they petered out. Yet we have been told that a low-grade ore can be found at the old site of Knoxville and Claraville up the river and at Elizabethtown on Martie Creek. There are some good-looking ledges near Bronco, and across the river from Truckee there is a lot of float quartz. Colors of gold have been found in the bed of the Truckee river, and so it seems that there is gold in this neck of the woods. But nothing has been done in the way of prospecting for many years. It might pay to prospect a little. There may be valuable minerals, or useful rocks found in this neighborhood, for there has been but very little geological work done hereabouts. We have been told of the existence near here of deposits of a volcanic rock which is fire-proof and again of a substance akin to kaolin, also of a substance resembling gypsum. How extensive these deposits are no one knows. It might pay to find out.—*Truckee Republican.*

WHOPER.—Yes, sir, that cat of mine could spring fifty feet after a mouse, and—Breakley (who stutters)—Whew, what a—l—l—l—Whopper—It is not a lie, and I'll knock you down if you don't take that back! Breakley (continuing calmly)—L—l—l—lively cat!

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

FROM SUTTER CREEK.—*Ledger*, May 23: Work about the Hector is being actively pushed. The 40-stamp mill is running to its full capacity on surface rock and dirt, of which there is a sufficient quantity to run for some time. The company intends to put up hoisting works in the place where but a short time ago they tore down the old hoist. The program, after the hoisting works are running, is to at once drain the shaft, do the needed repairing, and then proceed to crisscut and drift at the bottom, so as to determine what there is left in the mine at the present depth.

THE LINCOLN.—The lessees of the Lincoln are working hard to get the property on a paying basis if possible. The ore so far encountered is of a very low grade and, unless there is an improvement soon, the work will probably come to a standstill.

THE BELMONT.—The Belmont is looking encouraging from the appearance of the plates. The superintendent writes: Surface tunnel now in 300 feet, the last 10 being in the east ore vein. Upraise No. 1 has been started with a view of stopping above tunnel level, as the walls are too high, and will have to timber the same and do away with present open cut. Ten stamps are running and have lost no time the present month.

AT VOLCANO.—The Morseno Bros. have struck it richer than ever in their gravel claim, the Battle Mountain.

BAY STATE.—The newly-elected directors of this company held a meeting on the 18th inst. and organized by the election of officers as follows: W. T. Jones, president; W. A. Green, vice-president. It is expected to begin work about the first of next month, and certificates of stock will be ready to deliver to subscribers in a few days.

BELL WETHER.—After sinking to a depth of 100 feet, it was found impracticable to get deeper with the present facilities for controlling the water, which is very abundant. Accordingly they are now drifting for the ledge at the 100-foot level, and expect to reach it this week.

Calaveras.

TO HAVE A MILL.—*Chronicle*, May 23: The Lava Bed gravel claim, near Railroad Flat, owned by Lampson and Evans, has proven by the prospecting operations which have been going on for some time, that the deposit is extensive and rich. This having been established, preparations are being made to put up a five stamp mill on this mine.

THE QUAKER CITY MINE.—The water having all been taken out, the shaft repaired and everything put in order for work, sinking was commenced in the Quaker City mine, when a fine body of ore was encountered. The vein of quartz is about four feet in width, of the kind known as "ribbon rock." This is at a depth of nearly 400 feet. Mr. Tom Goodwin, the superintendent informs us that so far the outlook is very encouraging.

LOOKING WELL.—The Orchard mine at the lower end of town seems to promise well. At a depth of about 45 feet the blue gravel was struck, and on Thursday it was prospected and found to go 25 cents to the pan. The volume of water does not increase with the depth, but on the contrary seems to grow less. It is now easily controlled by the pump. At the present writing it is of course impossible to tell whether the main channel has been struck, or merely a wash that may continue or may not. It is supposed to be yet about 40 feet to the bedrock. If there should be this amount of gravel, all paying as well as the present prospect, this will be one of the richest mines in the vicinity.

SALE OF A MINE.—*Prospect*, May 23: The Shendoah Mining Co., composed of Oakland parties, have purchased what was formerly known as the Hoosier mine, now the Shendoah, located near the Calaveras river, above Jesus Maria. The mine has been operated under bond by this company for more than a year, with William Craih as superintendent. The outlook of the mine warranting it, the purchase of the property was consummated this week.

GOOD ROCK.—The rock recently crushed in the Campbell mill at Murphys that was taken from the Wood's mine is reported to have gone \$35 per ton free gold, besides a large amount of exceedingly rich sulphurets, 1600 pounds from 16 tons.

PROSPECT FOR WATER.—H. S. Blood made a trip to his place at Bear Valley last week and reports four and one-half feet of solid snow all over the country. This snow fell early in the season and will not run off at the first glimpse of sun. This will keep the head streams of our rivers plentifully supplied with water late into the summer.

REPORTED SOLD.—There is a report that the Osborn mine at Albany Flat near Altaville has been sold. This is likely to be one of the best paying properties on the Mother Lode as the deposit is very extensive and the rock very rich.

El Dorado.

SEARCHING THE GOLD BELT.—*Genetown Gazette*, May 21: H. W. Turner of the United States Geological Survey will shortly leave San Francisco for extensive investigations in the gold belt of California. His work is not as important in the view of exploration as that now being carried forward in Alaska, but it is of great moment as bearing upon the mineral resources of the State. The State Mining Bureau is now conducting operations similar to that in which Mr. Turner will engage. The two results, separately obtained, will be valuable for comparisons in the same field. D. P. Gray came up from Oakland during the week to be present at the starting of the mill on the Gray and Bosquit claim. Everything is now in complete working order, and the mill has started to crush the eighty tons of rock now on the dump.

Inyo.

DOING WELL.—*Index*, May 20: The Enterprise Mining Company, at Redding Canyon, has just shipped a car-load of ore to Salt Lake for reduction. It assayed \$8 per ton. Four men are at work in the mine, the lode being eighteen inches wide. Owing to the large amount of ore, soda, borax and marble being shipped from Inyo county, an extra engine has to be sent from here to Ham-mill station once or twice a week, to help the regular train over the summit of the White Mountains.

Lassen.

DIAMOND MOUNTAIN MINES.—*Advocate*, May 21: On Tuesday last the Honey Lake M. & M. Co. started up the 10-stamp mill on Gold run creek, on ore from the Superior and Gray Eagle mines, and expect to keep it running all summer. They have about 250 tons of ore on the mine dumps and will keep a force of men extracting ore from both mines for the balance of the year. Supervisor Perkins, W. B. Long, L. H. Peck and Thurston Thomas are the leaders of the enterprise, although there are several other stockholders residing here, and others in the East. The prospects for a profitable run are flattering, and we hope for the good of the company and this community generally that the highest hopes of these enterprising gentlemen may be fully realized.

Nevada.

THE CENTENNIAL.—*Transcript*, May 25: Superintendent Richards of the Centennial says that to the last upraise above the new tunnel, at a distance of about 12 feet, he cut into a fine body of gravel, rather dry and much cemented. It is as blue as indigo. He took out about a carload of the gravel and the cleanup of it shows numerous lots of fine heavy gold, such as should be found in the main channel. The pitch of the bedrock is toward the face of the tunnel, which should cut it in running about 100 feet farther. Capt. Richards has sent a sackful of gravel to the office in Gold Hill.

PEABODY MINE.—The new shaft on the Peabody mine is now down 200 feet, and is a fine piece of mining work, and has been sunk to an even incline of 36 degrees. The shaft has to be sunk 50 feet more to reach the bottom level.

Placer.

EXTENDING THE WATER SYSTEM.—*Republican*, May 20: The South Yuba Water Co. has made some extensive improvements on its property in this county since Jan. 1st. In Auburn the company has laid 200 feet of four-inch pipe, mostly on Commercial street, through Chinatown and over the College tract, and the cost of improvements in the Auburn district has been \$2000. In the Clipper Gap district the tunnel has been cleaned out and retimbered, and the improvements made in that vicinity have cost \$700. In the Gold Hill and Ophir district \$225 has been expended in rebuilding the flume near Bear river and cleaning out branch ditches. Around Newcastle and Plumas all the branch ditches have been cleaned out at a cost of \$1132. At Penryn 700 feet of 11-inch pipe has been laid. Other improvements here and there have cost \$3380 since the beginning of the year, making a total of \$7937 in addition to running expenses. On Monday the company sent off an order for 2100 feet of four-inch pipe, which is to be laid to the town of Lincoln. It is not expected that there will be a shortage of water anywhere this summer.

Plumas.

STRUCK GRAVEL.—*National*, May 23: On Thursday afternoon news was brought to town that gravel had been struck in the Slate Creek mine, owned by Halsted & Swiggart, and located on Hungarian hill. These gentlemen have been engaged in running a tunnel since July last to tap this channel, which could be traced on the surface for a distance of a mile and a half. They run in 720 feet, breaking through into gravel 204 feet from the surface. The gravel looks favorable and they seem confident that they have struck a bonanza. This development is in a rich and paying section where thousands of dollars have been taken out in years past, and where, it is hoped, thousands may yet be brought forth.

NEAR GIBSONVILLE.—Work is progressing at the Thistle shaft. Mr. C. B. Wingate, the managing superintendent left for the lower country last Friday. They are working eight-hour shifts in the tunnel, Mr. F. A. Gourley having charge of the works.

DRIVING TUNNELS.—East and southeast of the Genesee mine there rises to the height of 1000 feet a mountain of metamorphic rocks, seamed with stringers of rich gold ore, iron and copper stained, and in some cases containing a high percentage of good sulphurets. Heretofore all the prospecting on this hill was done on its very top, affording little opportunity for successful mining—a fine field, in fact, for a waste of muscle, energy and time. At present, however, tunnels are being driven into the hill from its base and better things may be looked for.

San Diego.

MORE CEMENT KILNS.—*Union*, May 21: Work is being hastened at the Jamul cement factory. President Warren Wilson says, on the five additional kilns that the increased business of this new industry demands. They are getting the fire brick from the South Riverside company, 105 tons being en route, instead of sending to San Francisco as was done for the two first kilns. Ten tons of boiler iron has been ordered from San Francisco for these new kilns. The first hatch of cement turned out was used six weeks ago to lay the pavement before the north side store room of the George J. Keating building on Fifth street, and shows that the Portland cement of San Diego county is somewhat darker than the imported Portland adjoining it. Experts say that the local cement is more of a true Portland color, being a dark bluish brown. Prof. Leonard of Los Angeles, writes that the carload shipped them was eminently satisfactory, and he would like all that can be had. The professor thus corroborates his first estimate of the cement, as it was he who made its true quality known. Another carload has been forwarded for the beet sugar factory at Chino.

Shasta.

COAL DISCOVERY.—*Free Press*, May 23: An important coal discovery is reported near Eiler's ranch on North Cow creek. A gentleman named Jay Conklin has opened a vein of coal five feet thick and of splendid quality. The lode or strata lays 60 to 100 feet under solid sand rock, and is not mixed with clay, as are all other finds in the locality heretofore mentioned.

IRON MOUNTAIN.—The Iron Mountain mill started up last Monday, but broke some of the machinery in a short time, and work was again shut down for a week or two.

FROM IGO.—Work on the Crystal tunnel has been delayed by accidents and sickness. The first ledge, about thirty feet from the one being run far, has just been cut, and shows fine ore. Robinson & Co. have rebuilt their arrastra, and have been running on South Chicago ore. They are now get-

ting a car load of silver ore ready to ship from the Pearl. Wm. Streater has found several ledges on Sec. 21, near the Lee place. He has built himself a cabin, and is at work taking out some good ore. D. H. Hubbard is running his arrastra on Cold Spring ore. Shirland Bros. are running their arrastra on Creighton ore. E. L. Ballou's arrastra is running on Manzanita ore. W. P. Litten is getting out ore at the Continental, and will start up his arrastra soon. Charley Rossie is grinding ore from his new find on Andrew's creek. Doc. Dunham is running a tunnel on his Muletown ledge with good prospects ahead.

Sierra.

NEAR SIERRA CITY.—*Mt. Messenger*, May 23: There was a large cave at the Mercer & Salines quartz mines a few days ago, wrecking chutes and covering considerable pay ore with debris. The damage was not heavy, but will somewhat lessen this month's cleanup; the previous one was very good. There is abundance of ore at the Young American No. 4 tunnel, but thus far, very little gold in the quartz. A rich chimney may though he struck most any time as this is the heart of the gold belt. The ever energetic and persevering owners have the best wishes of the people, at home and abroad, for a golden winning with the spring roses. The Sierra Buttes Co., 'tis said, will soon be 'getting a move,' rebuild their upper mill and employ about 60 or more men when—some of the far-away, long absent boys may "come home again."

DRIFT MINE.—Capt. Meikle was over from the B. M. Ex. mine, Wednesday. He has not yet been able to get any lumber either for the purpose of building a reservoir or for a foot plank for the track. During the past ten days he has put in a 200-foot turnout which will hold nearly all the cars which the company has at present. When drifting is begun, both up and down the channel, gravel coming from both ways will be made up into trains on this siding, to be taken thence to the dump by mules. The last raise put up to gravel exposed a heavier wash than either of the others. At this point the bedrock was a trifle lower than at the shaft raised just before, and the gravel is the best looking that has yet been found. It has not yet been possible to do anything toward making a large dump. It is at present proposed to work the channel entirely through chutes. A tunnel will soon be started from the present tunnel up the channel with a heavy grade, and another down the channel with just as light a grade as will carry off the water encountered. This will be almost equivalent to two mines, and will enable the management to much sooner put on a large force. By this manner of working there will be no necessity of leaving any gravel pillars to support the main tunnel, but when a convenient distance has been worked another chute can be raised and all behind it abandoned.

Siskiyou.

QUARTZ DISCOVERY.—*Journal*, May 23: The discovery last week of a five-foot quartz ledge on the west side of Langell valley by Mr. Anderson of Lost river has set the mining element agog again, and it is now predicted that this country will be found to be full of paying mineral veins when the miners thoroughly prospect it.

WILL NAVIGATE THE DITCH.—The Little Klamath Ditch Co. proposes to operate a small scow bottomed steamer on their new 40-foot ditch when the same is completed, which will be a great convenience to dwellers at Tule lake and vicinity and which cannot fail to prove a profitable investment.

Sonoma.

PINE FLAT CINNIBAR MINES.—*Tribune*, May 21: O. C. Huebner is engaged in surveying the Red Buck mine, the property of W. F. O'Leary and Jas. Condran. It is said that Hassett intends building a large furnace at the Hoffman mine. John Swift & Co. have contracted to run a tunnel 200 feet, an extension of the Crystal mine. By a 65-foot cut a rich ledge, three feet, six inches in thickness, was reached in the Crystal mine a few days ago. It contains five per cent mercury. Ore of two per cent quicksilver is penetrated by the 140-foot tunnel. Excavation of seven feet more in this tunnel, it is expected, will reach a very precious ridge. The proprietors of this mine are highly elated over the prospects and as soon as possible operations will be commenced. Mr. O'Leary is assiduously engaged in preparing for the operation of his mines and it is hoped that his endeavors will meet with success.

Tuolumne.

POCKETS.—*Independent*, May 23: Warren Stinchfield struck a pocket in his mine, at Jackass Hill, on Thursday last week, from which was taken out the sum of \$2000. Good prospects are reported in the Sell pocket mine.

WILL TEST IT.—It now seems as if the owners of the Calaveras mine, at Robinson's Ferry, have set to work in earnest with the evident intention of finding out what is in the mine. The mine is a good one and only requires push and coin to prove it.

NEVADA.

Washoe District.

ON THE COMSTOCK.—*Territorial Enterprise*, May 23: The 1400 level station of the Potosi winze has been cut out, and prospecting on this level has been commenced. The interest in the situation at the Potosi will be maintained until the country is fully prospected to the water level. A strike of a body of ore in Potosi would give the market a strong backbone.

CROWN POINT.—The north drift from the 300 slope, eleventh floor, was continued to a total distance of 41 feet. Nothing of importance was encountered. An east crosscut was then started from the south end of the sixth floor, which is now out six feet. The face is in a mixture of clay and quartz, giving low assays. The 1000 level east crosscut from the main south drift, having been extended twenty-six feet during the week, is now out a total distance of 104 feet; the face is in soft porphyry.

CHOLLAR.—The south drift, 1400 level, from the north line, is out 110 feet, face in porphyry. The winze in the joint east crosscut, north line, 1400 level is down eight feet; the bottom is in porphyry. Extracted and sent to the mill the past week 539 tons of ore worth as per battery samples, \$18.10 a ton.

POTOSI.—The winze is down 103 feet below the

1400 level; the bottom is in porphyry and streaks of quartz. The south lateral drift from the winze station, 1300 level, is out 228 feet; face in porphyry. The south lateral drift from the Chollar incline, 1100 level, is out 172 feet; face in porphyry.

WARD COMBINATION SHAFT.—The south drift from the 1800 station is out 22 feet in hard porphyry.

NEW YORK.—North lateral drift, 600 level, is in north of shaft 270 feet; face in porphyry. North lateral drift, 1100 level, is out north of shaft 494 feet; face in low-grade quartz.

SILVER HILL.—The southwest drift, 50 level, is out from shaft 40 feet; face in porphyry and quartz. South crosscut, 160 level, is out from winze 535 feet; face in hard porphyry.

ALPHA.—The winze 80 feet north of shaft, 500 level, has been connected with the 600 level.

EXCHEQUER.—The east crosscut on the north line, 600 level, is in hut 204 feet, face in porphyry.

UNION SHAFT.—West drift from the shaft, 900 level, is out 212 feet, making 53 feet during the week; the face is in hard porphyry.

SAVAGE.—We have hoisted 586 cars of ore from the 500, 750, 800, 950 and 1400 levels. Shipped to the Mexican mill 534 tons and milled 440 tons; average battery assay, \$16.49. We have haulion on hand amounting to \$13,883.96. The G street tunnel has been advanced 40 feet since last report, making its total length 540 feet. The Ophir Mining Company has received a shipment of four bars of bullion, valued at \$4,261.75, being the product of 835 tons and 1600 pounds of ore worked at the Morgan mill. The yield of the ore in bullion per ton was \$15.86, of which \$5.94 was gold and \$9.92 was silver. The average assay of the value of the samples per ton was \$26.41.

ALTA.—The mill is now working five stamps on ore extracted from the old reserves above the 900 level.

YELLOW JACKET.—Are shipping about forty tons of ore daily to the Vivian mill, and preparing to extract gold-bearing rock for shipment to the Santiago mill.

JUSTICE.—The usual prospecting work is reported from this mine during the week, with nothing of importance to note.

SIERRA NEVADA.—630 level: West crosscut No. 1 from the northwest drift, 571 feet from the shaft, has been advanced 35 feet; total length, 477 feet. The formation is and has been hard.

UTAH.—Incline winze has been sunk 24 feet; total depth, 64 feet, continuing porphyry, clay and quartz, assaying low in the precious metals.

ANDES.—On the 420 level east crosscut from south drift has been advanced ten feet; formation vein porphyry. East crosscut from the north drift on the 420 level has been extended sixteen feet; face in quartz.

The Gould & Curry, Challenge, Best & Belcher, Hale & Norcross, Con. Imperial, Belcher and Seg. Belcher are all actively prosecuting their usual amount of exploratory work.

Candelaria District.

THE HOLMES MINE.—The company is now extracting ore from the 2100-foot level of the Northern Belle mine at Candelaria, and obtaining a rare kind of silver ore that is a pure turquoise in color and quite rich. The mine at that depth continues, as it has from the surface, to be as dry as a powder horn, and there has never been a drop of water encountered in it.

Esmeralda District.

VARIOUS MINES.—*Walker Lake Bulletin*, May 20: In the Lapanta mine a fine body of \$80 gold ore is being opened above the level of the old tunnel. Drifting northeast on same at present, toward the dyke. The ore is holding strong, and quite a large body is opened to be stumped. An incline is being sunk below the tunnel, and is now down sixty-five feet, following under the gray cap. It shows a fine ledge in the bottom, which is now carrying some gold, and rich ore is expected in the next eight or ten feet. In the Pamlico the main tunnel is being driven ahead and some fine ore taken out. From the Central a large amount of high grade lead and silver ore is being extracted from the main incline and the slope south of it. Considerable gold ore is being got from the same slopes. The soft part of the ledge is high grade gold. On the Hartford an incline is being sunk on the vein, the ledge being from eight to ten inches wide, the ore running from \$40 to \$50 gold.

CHALLENGE.—The tunnel is being run on the vein exposing a good-sized ledge. Considerable 175-ounce ore is being extracted.

WAR EAGLE.—Fair grade of ore is being extracted. Two car loads will be shipped this week.

White Pine District.

LEAD ORES.—*White Pine News*, May 19: The miners of White Pine mountain have about 600 tons of lead ores for shipment to Salt Lake. The ores of White Pine are heavier in lead than those of any other section in the west.

DEEP CREEK.—We have heard of no miners or others in this section being carried away with Deep Creek excitement. One reason for this no doubt is that our people know something of that country, and another, that they believe the mining field here at home is better than that of Deep Creek.

CHERRY CREEK.—Letters from Cherry Creek state that the new mill at the Star mine was started up last Saturday and is running nicely. So far as tested the concentrates from the dump are said to be a paying investment. All of which we are really glad to note.

ALASKA.

FROM THE MINES.—*Juneau Record*, May 7: The Silver Queen Mining Co. is doing good work on their Sheep Creek properties and is pushing everything ahead as rapidly as possible. The 10-stamp mill is completed and soon will be in running order. Work will soon be commenced on a tramway from dump to the ore bin on the flat, after the completion of which the mill will be started. During the past two seasons this company has shipped ore below for treatment and has received handsome returns and is now thoroughly satisfied with the true value of the property and will henceforth operate it on an extensive scale. During the week T. D. McMannus and James McDonald returned from a prospecting trip and brought in some very fine silver rock. The ledge is about five feet wide and can easily be traced for a considerable distance. The

are free milling and the ledge crops out on the beach where vessels can anchor within a stone's throw. There is plenty of water and timber in close proximity which will greatly facilitate the cheap working of the mine. It is their intention to do considerable work during the summer. It is reported that Richard Willoughby is about to make a sale of his Admiralty island property to a syndicate of mining capitalists. Last year Mr. Willoughby erected a small mill on this property and made a short and most satisfactory run and if the property should change hands it is probable that more extensive works will be placed thereon. There are many good mining properties on that island which are only waiting capital to turn them into dividend paying concerns. Mr. Thomas Mein, superintendent of the A. T. G. M. Co., returned on the Mexico and has again assumed charge of that company's gigantic mining works. The warm rays of the sun are having a great effect on the snow and slides can be heard in all directions. Monday a large slide came down the mountain this side of Sheep creek, just opposite Treadwell's piling now on the beach to a depth of about 60 feet. Wm. Antisell will open his assay office in a few days in the room next door to John Prior's place of business on Water Front. On the arrival of the Topeka it is expected that many of Alaska's mining men will return to engage in the mining industry during the summer. Chas. Forrest is engaged in running a tunnel on the Salmon creek properties owned by Messrs. Maloney, Gamel and others.

ARIZONA.

MINING NEWS.—*Journal-Miner*, May 20.—The Tiger mine is in splendid condition, there being an abundance of ore in sight in all the workings. The Big Bonny is pronounced by experts to be the finest and clearest quality of any yet discovered. J. W. Dougherty returned yesterday from Big Bug, where he procured about 1½ tons of onyx for shipment to the Smithsonian Institution at Washington. The onyx was shipped this afternoon. J. H. Hamilton, A. P. Smith and Scott Greening purchased the Rich Hill mine belonging to the estate of Wm. Johnston. The latter, it will be remembered, was buried alive in his tunnel, in November last, and efforts to reach him proved fruitless. The new owners will, however, now work the property. Prof. Douglass will leave in a day or two for a visit to Bisbee, but will return here in time to start up the Copper Basin plant in a few weeks. Experimental runs of this property have proven satisfactory. The Copper Basin works will be started up now within a few weeks. The plant recently put in there is a very extensive one and is said to be very complete. Work on the dam of the Lynx creek hydraulic company will be commenced in a few days. The volume of water in the creek at present is too great to permit of the work being commenced, but is decreasing rapidly. Twelve men are engaged at the Blue Dick mine taking out ore for shipment. This mine has never yet failed to respond and yield a dividend for its owners when worked. There are about 25 tons of ore on the dump now awaiting shipment to the sampling works.

BRITISH COLUMBIA.

A RICH DISTRICT.—*Inland Sentinel*, May 23: Spilliamacane mountain, 1½ miles from the river and about 40 miles from Golden, says a correspondent, is practically a mountain of concentrating and smelting ore. Galena lodes running from 30 to 80 per cent lead and 20 to 40 ounces in silver; copper veins assaying from 30 to 80 per cent, and from five to 30 ounces of silver abound on it, and this is only the result of the croppings, as no depth has been reached on any of them yet. Mr. McCrae has been working on those two mountains for the last four years, but like the majority of the claim-owners, has only just been able to keep up his assessments. He has unbounded faith in them, however, and says all they want is a little capital and they will have the richest country in America.

THE NORTH THOMPSON RIVER.—This river up to date has not been prospected to any extent. The few who have gone up the river in search of ore have succeeded in their mission, and those who will follow may reasonably expect a like share of fortune. The North Thompson district lies between the vast placer mines of Cariboo and the Big Bend country, and is easily accessible. It is one of those regions which is naturally of rich mineral wealth, and has not been gone over by the prospector. We fear that the lack of success of prospectors is too often attributable to the fact that they go over ground which has already been covered, the infatuation of their business leading them to hope that they may hit upon something which those who preceded them have passed by. Here is a district lying between two of the richest mineral sections of the province as yet developed, and still remains practically unprospected. If the Westminster Co. would turn their attention to the North Thompson they would do well.

COLORADO.

VARIOUS MINES.—*Georgetown Courier*, May 19: About 400 feet west of the Grant tunnel and 30 feet higher, was driven the McNulty tunnel a distance of 300 feet, which intersected the vein showing about five feet of ore similar in character to that disclosed in the Grant tunnel. A drift has been run east 90 feet (toward the Grant tunnel) and west 120 feet, with the same ore body continuous throughout. Recently the Kohn tunnel has been started near the extreme east end of the property, and about 200 feet lower than the McNulty tunnel. After driving but 70 feet the lode was encountered just below bed rock, and a drift driven west 20 feet, which has two feet of first class ore in the breast. The ore upon the ground fills every bin and bouse that can be reserved for its accommodation. The soft snow has broken up the winter roads and for a little time makes it impossible to ship. Like all bonanza mines, wherever this mine is touched it seems to yield marvelously. From the Kohn tunnel on the east to the McNulty tunnel on the west is about 1100 feet linear measurement and 200 feet perpendicular, yet these workings and the intermediate workings disclose the same ore body. The Free-land mine, on Trail creek, has yielded up an ore body about 2000 feet in length, one of the largest, if not the largest found in this country. The Leadville-Pennsylvania promises to yield as large a body,

for the extension of the mine is worked by the same owners and is also yielding large quantities of ore. C. L. Billings had a mill-run from the American Sisters which returned in three classes as follows: First class, 136 ounces silver, .3 gold to the ton and 14 per cent lead; second class, 290 ounces silver, .25 gold to the ton, 8 per cent lead; third class, 126 ounces silver, .1 gold.

THE GREAT LEADVILLE-PENNSYLVANIA BONANZA.—From time to time we have spoken of the property owned by Col. Morrison, Ernest Le Neve Foster, Burton Hopkins and Mason Hall. It has now developed into one of the really big mines of Summit Co. and the output is estimated by carloads; in fact there seems no end to the ore body which has been opened up practically for 1100 feet in length and about 200 feet in depth. The properties consist of seven patented lodes, about three miles from the town of Chihuahua in Summit county. The main lodes are the Pennsylvania, Paymaster and Hall. The first development was by the Grant Tunnel started about the center of the claim, which at a distance of 65 feet intersected the Pennsylvania lode, disclosing from 5 to 7 feet of ore running about 40 ounces silver and 50 to 60 per cent lead.

BIG GOLD FIND.—*Aspen Times*, May 21: A big gold discovery has been made in the Gunnison, upon a branch of the Denver & Rio Grande railway. It has been known that gold-bearing quartz existed in the neighborhood, but only one miner stayed with his property, and he came to Denver and made a trade with some parties in the city, who have formed a company, and they intend erecting a large stamp mill near the mines as soon as possible.

Professor James R. Manes, a mining engineer, was sent to examine the property, and he says he was much surprised to see several large quartz dykes running due east and west, and some two miles from where these dykes cross the river, he found other quartz dykes running due north and south, crossing the first named dykes, showing that fine milling gold quartz is there in such quantities that many large stamp mills could be kept busy for many years to come, working night and day. Mr. Manes took some of the ore from one of the mines and had the same assayed, and had a mill run as follows: No. 1 mill runs \$10.96, No. 2 assayed \$48.80, No. 3 assayed \$84. "These were picked specimens," said Mr. Manes, "but all the ore will pay to stamp and plate much better than the Black Hills ore that is now being worked by the Home Stake and the Father D. Smith. Their monthly returns are very large, still the ore only averages about \$3 per ton.

AT THE IRON MASK.—Vast surface improvements are going on at present, consequently development underground is not as extensive; but as soon as the surface work is finished underground operations will be pushed with renewed vigor. The upper 150 feet of the tram has been torn up and will be sunk lower, in order to give the cars free access to the ore bins. Grading has been done for an office building for the mine, an addition to the assay office. The large crib for waste is finished, and a number of men are working on the switch of the tramway. Mine workings at present consist of three contracts: 6 and 10 levels and a raise at the breast of the incline. A raise run recently in No. 10 level, 10 feet back from where the drift resumed operations struck, in a few feet, a 6-foot body of lead ore, which will average 8½ ounces in silver, 20-100 gold and 54 per cent lead. The ore from No. 3 crosscut runs 378 ounces in silver and two ounces in gold. The mine is showing up remarkably well in every part, and is good for a prosperous year under its present management.

IDAHO.

BOISE COUNTY NOTES.—*Statesman*, May 19: This has been an unusually dull week in the Basin, as a great many of our people were at Boise City to witness the Presidential reception and shake hands with the bead personage of this great nation. Most of them have returned and are loud in praise of the royal manner in which they were entertained and shown around by the people of the thriving and beautiful capital of our young, and destined to be great State. Mose Kemper has brought to town several large specimens of ore from his mine, the Moscow, in Eldorado district, a few miles beyond the More creek summit, and two miles west of the Banner road. He had men at work all winter running a tunnel, which reached the vein a few days ago. The ore is very rich in silver, but only carries a very little gold. A large number of claims have been located in that district during the past two years.

MONTANA.

THE REGION ABOUT HELENA.—*Mining Journal*, May 20: The enlargement of the smelter plant at East Helena, mention of which has heretofore been made in the *Journal*, will consist, for the present, in the construction of additional roasters, work upon which will be commenced during the present week. The general manager, Mr. Raht, has the plans completed, and the construction will be vigorously prosecuted. Three stacks are now running, and the fourth being relined will be blown in within a few days. If the ore supply warrants, the promise now being that it will, additional stacks will be added to the plant this season. As yet there is no promise of the reopening of the Anaconda. Of the seventy-five men at work at the mines fifty-three were laid off on Monday by Mr. Daly, an action certainly not indicative of early resumption. The Summit mine in the Dog Town district is shipping ore. It is being loaded on the cars at Toston and this shipment will go to Aurora, Ill. The bottom of the shaft now to the depth of 215 feet shows seven feet of pay ore. Bud McAdow has returned to the Spotted Horse mine at Maiden and has added to the working force, thirty-five men at present being employed. There are eight shifts of four men each being engaged in sinking the shaft. The present force will be further increased this week. P. Larson has returned from a visit to the Helena and Frisco mine, and reports that the mine is looking well and that indications point to the indefinite continuance of regular dividends. This mine is assuredly a bonanza. Good reports continue to come from the Emery, or Carbonate Hill mine, in the Zosel district, Deer Lodge county. With the exception of Mr. Halteman, of Helena, the new purchasers are all residents of Deer Lodge. They are managing the property on a strictly business basis, confident of possessing a mine of permanent

value. The shaft of the Silver Dollar in the Park district has been sunk to the depth of about eighty feet, instead of ten feet, an erroneous statement that broke into the mining column of the *Sunday Journal*. The new host on the Bald Butte is finished and in operation, and the officers are now on the ground with parties with whom the company is negotiating for the erection of a new twenty stamp mill. Governor Hauser returned from a trip to Missoula and the Curlew Mine in which he is largely interested. He was, on his return, accompanied by Stoner Blake also one of the owners, it being upon his ranch that the mine was discovered. The mine is producing, and there is being put through the concentrator about 120 tons of ore daily, enabling the company to ship from nine to twelve car loads of concentrates monthly.

NEW MEXICO.

MINING MATTER.—*Silver City Enterprise*, May 22: Mr. Kellum is running his mill at Gold Hill and making it pay well. Col. Prichard is taking out good ore on the White Signal at Gold Hill. Col. Bill Wells, of Gold Hill, sold his Gold Dollar mine recently for a snug little sum. The Little Fanny Mining Co. has raised \$30,000 to develop the mine and improve its mill. Capt. J. N. Sawyer started the development of the Pacific mine, which he owns in partnership with Joe Sydenspinner. While sinking an air shaft on the Reservation at Gold Hill, ten inches of ore was struck which average \$150 per ton in gold. The American mine at Hachita has been closed down on account of the suspension of operations at the El Paso smelter. It will be some months before the smelter is again ready to blow in. The consolidated Nebraska Co. of Pinos Altos, has now reached a depth of 210 feet with its main working shaft, and will continue to sink 60 feet farther, at which point a crosscut will be run to tap the vein. At a depth of 40 feet the lead was carrying 15 inches of good ore, and if it continues at that width to the proposed depth, the company will have a mine that is worth talking about. The two smelters at Clifton have shut down owing to an insufficient supply of coke, caused by an accident to a bridge near hear. Mails have arrived regularly.

NEWS FROM THE MINES.—*The Pinos Altos*, May 22: The Mountain Key is nearing the 700 foot level and is looking fine. The crosscut from the shaft to the lead, 50 feet in the Kleptomania mine, will be completed next week. The Huston & Thomas mines are being worked with a full force. The Long Brothers are taking out some fine ore and are running it through an arrastra with satisfactory results. The excavating in the Mammoth mine is completed and everything is in readiness for the stamps, which are expected any day. The Kleptomania is at this writing in splendid shape and capable of putting out all the ore the company can handle, and fine ore at that. John McDonald, owner of the Arizona No. 2 mine, is driving a tunnel to connect with the main lead. He is in 285 feet, and as soon as he gets under a 135 foot shaft will make an upraise for air. This property is looking fine. Williams and Burton, who are contracting on the first level of the Kleptomania have struck it rich. Some time ago they run into a fine though small vein of ore which has steadily widened, and now they are stopping and drifting on as pretty a lead as can be found in the camp. The Wagner mill, after having lain idle for some time, is undergoing necessary repairs and will start up again some time the coming week on ore from John McDonald's mine, after which ore from the Bennett mine will be worked. Jack Magee, Silver City's efficient boilermaker, is superintending the work, which is a sufficient guarantee that the work will be well done. The first carload of ore from the Golden Rule mine, in Arizona, arrived this week and will be run through the Bell & Stephens mill in a few days. This will be a test run, and while the ore itself is rich and carries considerable free gold it is uncertain whether it can be successfully worked here. However, a few days will decide the matter, with the probabilities all in the affirmative.

OREGON.

FROM THE MINERAL DISTRICTS.—*Times*, May 22: The mines of Baker county will yield handsomely this year. Prospectors are leaving the city daily for the various mining districts. Another rich pocket has been struck in the Blackwell district near Willow Springs, which bids fair to prove a bonanza. Full particulars are not yet furnished the public. M. L. McCall of Asbland has located a quartz ledge in the neighborhood of Gold Hill, which bids fair to prove valuable, samples of the ore showing free gold to the naked eye. G. W. Houck returned from a trip to Southern Oregon the forepart of the week. He showed us a fine quartz specimen taken from the ledge of his son, Jesse, in the Gold Hill district. He also had some specimens of iron ore unearthed near Monroe in this county, which promises to be of great value. W. F. Davis left for Cornucopia Monday morning. He goes to examine the remains of his mill, which was destroyed by a snowslide last winter, with a view of putting it on its feet again.

CINNABAR.—The capitalists who are interested in the development of the quicksilver mines in the Cinnabar region made them a visit last week and were delighted with the prospect. We are informed that they will soon put a large force to work and make arrangements to operate on a large scale. It is the general opinion that those mines will yield big returns if worked properly.

SOUTH DAKOTA.

COPPER AND SILVER MINES.—*Deadwood Pioneer*, May 19: The reporter of the *Pioneer* has obtained from the superintendent of the Deadwood and Delaware Smelting Co. the following information in regard to the plant, operations and mines: Our claims consist of the Sonora and the Two Bears. The outcrop of the Sonora is about 200 feet east of the Oro Fino and dips toward it. The Oro Fino is vertical. At a depth of 250 feet the dips would bring them together. From the bottom of the Oro Fino shaft at a depth of 230 feet, we ran a crosscut to the Sonora and cut as handsome a vein of ore as has been discovered in Custer county, except that we have 18 feet of solid ore between two smooth well defined walls. The ore is a mixture of zinc-pyrite and galena, carrying both silver and gold. It is low grade, but the lead separates by mechanical

separation nicely from the iron and zinc, and when so concentrated has a value, where we cut it, of about \$80 per ton. The ore body is at least six times as thick as the Judd discovery, where I saw it, over which there is so much talk. We can trace the vein about 2,000 feet upon the surface. The smelter as at present designed, includes crushing and sampling works for about 250 tons of ore per day. Two water-jacket furnaces each three by seven feet, and two reverberatory furnaces each having hearths 12x15 feet. The furnaces have some peculiarities of their own as indicated by our last summer's work. We shall begin work with only one of each of the furnaces. The works were designed so as to be extended to 500 tons daily, should occasion require it. Your other questions concerning cost of plant, cost of treatment, amount and kind of flux, and what we propose to do with the matte, are matters pertaining to the company's private business and do not concern the public. I decided to answer fully your questions concerning the mines in hope that others will prospect elsewhere upon the same lines, for should lead be discovered and mined in sufficient quantities our works can be changed to lead smelting works like those at Omaha, upon ten days notice. The owners, the Swift Bros., and Pennypacker, will be here June 3rd and decide many things now unsettled.

UTAH.

MINING NOTES.—*Park Record*, May 23: The Ontario mill shipped 43 bars bullion this week containing 27,385.69 fine ounces of silver. The Ontario company is engaged in washing away the dumps at Nos. 1 and 2. This is an annual performance and is rendered necessary to make dumping ground. The operation generally carries considerable good ore down the creek and makes money for miners who follow jiggling for a living. The following lots of ore were received at and forwarded from the Macintosh sampler during the present week: Ontario, 635,620 pounds; Daly, 276,420; Anchor, concentrates, 298,200 pounds; A total of 1,210,240 pounds. The large Knowles pump expected by the Ontario company for use on the 1500-foot level, arrived this week and will be taken up to the mine early next week. The Kentucky leasers have finished re-timbering the old portion of the tunnel and are again working in the face. The vein is expected to be encountered almost any day. Monday last Engineer Langford tried the new tramway engine, after devoting a few hours to getting her in shape. The machine works like a charm and climbs the hill without an effort, barring the fact that on one or two of the shortest curves she binds a little on her trucks. That feature can easily be remedied and was one of the defects of the old engine. A few hours careful labor will place the new engine in first-class shape and capable of doing all that was expected of it. There are tons and tons of second-class ore and a large quantity of first class already stowed out and stored, and when the property is well opened out and the force increased the shipments will be large, rich and constant. It is entirely in keeping with Rebellion hill that the Roaring Lion should develop into a rich producer, and even if the coming summer should fail to see it such, the coming year surely will.

WASHINGTON.

AMONG THE MINES AND MINERS.—*Okanogan Outlook*, May 13: There are 40 men at work on the First Thought and the force is being increased every few days. The Lone Star is again in active operation. The water has all been removed and preparations are being made to prosecute work in both the 200 and 300-foot drifts and also in the main shaft. By the first of next week there will be fully 20 men employed in and about the mine. From the drift in the 200-foot workings of the Fourth of July, Prof. Reilly, who recently bonded a group of mines on Mt. Chapaca, came to town this week and was interrogated by a reporter as to the progress of development on the mines. The tunnel is now in 45 feet. Two shifts are being worked at present, but another will be added in a short time so as to expedite the work as much as possible. The ledge is between 10 and 12 feet wide, and the tunnel is now in a four-foot vein of good pay ore, assaying from 75 to 150 ozs. per ton. The ledge matter is trachyte and the country rock on both sides is granite. It is principally a gold ore, but carries some silver. Work will be prosecuted on the tunnel all summer. C. H. Ballard, who has the contract for patenting the Ivanhoe group of mines, returned from Palmer mountain Saturday after making the final survey of the group. "This is the first instance that has ever come under my personal observation where mining has been done with a plow and scraper," said Mr. Ballard, who always grows enthusiastic when speaking of this mine, and they have shown up more actual wealth in a few weeks in this manner on the Ivanhoe than could be done by the expenditure of thousands of dollars on any other prospect I know of. They have now a space uncovered of 72x117 feet, exposing that much surface on the ledge, which is lying nearly flat on the ground and averages 18 inches in thickness. It is all pay ore, and the whole body will average about \$100 per ton. It is estimated that there are between 800 to 900 tons uncovered and on the dump which is worth at the least calculation, \$80,000. About \$30,000 worth of this will be sorted and shipped during the summer. It is the intention of the owners to ship only enough ore to pay for prospecting the lead and putting in a mill. They will first prospect the lead by sinking a perpendicular shaft at a point 80 feet west from where the ledge has been stripped. From the dip of the vein it is estimated that 100 feet will tap it. If not, they will then drift to the ledge and then crosscut it. The shaft is already about 45 feet down.

WYOMING.

FROM THE GOLD FIELDS.—*Review*, May 21: Charles B. Loomy of Larimer, has lately visited the Gold Hill fields, and reports everything there in a promising condition, though the snow had not yet disappeared. Most people are taking hold of placer-mining. The Leviathan is down over 100 feet. The character of ore is unchanged for the entire depth. The enterprise improves in the quality of ore as it goes down. It shows a great deal of silver. The Cummins City stamp mill has been taken to Gold Hill and will be put in operation soon.

MECHANICAL PROGRESS

The Largest Stove Factory in the World.

In Detroit, Michigan, there is a stove foundry that is remarkable in many particulars. To begin with, it is the largest concern in the world devoted exclusively to the production of stoves. It is called the Michigan Stove Works. About 1300 men are employed and 70 tons of iron are daily melted and made into stove plates, the works making it a practice to so arrange their business that the amount of work done per day is pretty nearly uniform throughout the year. The foundry floor is equivalent to a floor 640 feet square. About 250 different styles of stoves are made. A correspondent of the *American Machinist* gives a very elaborate description of these works, from which we condense.

Testing the Iron.

All the iron used in this establishment is carefully tested by a skillful expert. The iron is tested in the form of bars, which are strictly confined to bars of one size, viz., 3" square and 12" long. These bars are tested in two different ways—by impact and by a steadily applied load, the machines being so arranged that each of them automatically makes a graphic record of the behavior of the test bar, its deflection, permanent set, and the stress which finally breaks it. This is accomplished by surprisingly simple machines, but in which there has been great ingenuity displayed.

This firm has added materially to the general stock of knowledge concerning irons, and may be expected to add more, and to help in diffusing that knowledge among the men who can make the best practical use of it.

A New Method of Making Stove Patterns.

A very peculiar system of making patterns for stove-plate work has been introduced there which is worthy of notice on account of its ingenuity and the results accomplished by it.

The old method of making stove-plate patterns, and the one which is still followed in most foundries almost universally, is to make the first pattern of wood, the outside being first carved into shape and then the back or inside to correspond, so that the pattern shall be uniformly of the specified thickness, usually one-twelfth inch. When the pattern is highly ornamental and intricate, as most stove-plate patterns are nowadays, the reverse side is much the most expensive to make, because its thickness must be constantly gauged as the work goes on, this gauging being anything but easy, especially where the pattern, besides being intricate, is of large size. This wood pattern is used but once, usually, the casting made from it being finished up for regular use in making stove plates.

By the improved method the form of the outside of the pattern only is carved on a block of wood, and this is then covered by a preparation of wax, which is put on soft in a number of coats of uniform thickness. It then hardens, and is removed from the carving, one side (that which was next the carving) being then exactly the right shape for the inside of the pattern, while the other is right for the outside, and it is of precisely uniform thickness. It is stiff enough to retain its shape well, and is, when thoroughly hardened, covered all over with a thick plating of copper, deposited by an electroplating process, which is analogous to that of electrotyping, if not precisely the same. This copper is also of precisely uniform thickness, of course, and the result is a pattern which is in every way much superior to a wooden one, because the copper easily takes a fine finish which is conducive to exceptionally smooth castings for the regular foundry patterns, and which require much less labor to finish than is the case where they are made from wood patterns. The copper pattern is unaffected by dampness, and is much more liable to be the same as when first made, in case it should be required for use a long time after being made. The pattern is much stiffer than would be expected. It was evidently much stiffer than a wooden one of the same thickness. The correspondent did not know whether the process would be applicable to any other kind of work, and thinks that it is covered by patents, but at any rate it was a matter of considerable interest to him, and he supposed it would be to most mechanics.

The Machinist's Shibboleth.

To form an estimate of a machinist's ability, in these days of improved methods, is not so easy a matter as it was 30 years ago. Almost everything is now done on machine tools, and the hammer, chisel and file are little used. In the old time, it was by his manner of using these that we were accustomed to gauge the skill possessed by the new man. If he took hold of his hammer handle at the middle, and struck as if his elbow had no joint, or took up a file with his thumb under the handle, and shoved it across the work with a teetering, jerky motion, he would at once be put down as an impostor.

Sometimes worse hindrances than these were committed. For instance, grinding the cutting edge of a drill on the wrong side, or attempting to put a belt on a pulley from the wrong side.

The file test is a good one, and if followed up, may put to shame some who claim to be good workmen. We wonder if one in ten of

the thousands of machinists who read your paper can file a spot on a round iron bar, perfectly straight, crosswise. We have seen such a surface concaved by the slight rotundity of the file. One of the interesting features of this performance is the nice vibratory movements of the joints in the arms and body that are necessary to secure the perfectly parallel motion of the file. Comparing these with the mechanism in the beam engine, the latter is very simple, for in this there is but one point to be kept in a parallel line (the crosshead), while with the file both ends must be controlled and held true to a line. Yet the operation seems very easy when, by practice, the art is acquired.

The plumber takes pride in his "wiped joint," the Slater in shearing and punching his brittle material like so much putty, the blacksmith his perfect weld, and the machinist will ever esteem his dextrous use of the file as one of his best proofs of skill.

One of the modern tests, we believe, is the use of the scraper; and the fitting together of two surface plates so perfectly that they can only be separated by sliding them apart, may be considered no mean art.—*Scientific American*.

JAPANESE SKILL IN METAL WORKING.—The Japanese are past masters in the treatment of alloys both in texture and in color, and no better guides exist. They achieve their grand results by the simplest means—a judicious blending of various metals, inlaying and pickling. Copper is the basis of their chief alloys, and by incorporating with it certain proportions of gold and silver they obtain remarkable results in color through the pickling process. But not only do they get striking effects from their alloys and pickling—their mode of working up the metals is a thing to be studied. For instance, they will take six or seven plates of different metals and alloys, weld them together, and then, by drilling, punching up, and filing, get a surface in which all the metals show in a manner which is truly wonderful. By the range of tints at their command they can work out on a metal surface scenes of animal life, landscapes, etc., with effects never dreamed of by metal-workers in the Western world. Among some examples recently shown in England was a knife handle on which was a representation of a duck dipping its head under the water of a stream on which it was swimming, the arrangement of the different alloys by which it was composed and the pickling being so well arranged that the neck of the duck was seen as under the water, when the handle was held in a certain light. Another example was a sword-hilt on which some minnows not more than one-sixteenth of an inch in length, each having a pair of gold eyes, were swimming upon a gray stream, the effect of their being actually below the surface of the water being suggested with marvelous skill. Imitations of wood, grain, and marbles were also shown.—*Jeweler's Weekly*.

TO COLOR BRASS WORK.—A beautiful violet color is imparted to brass work by the application of chloride of antimony, says a writer in *Work*. Get the work perfectly bright and clean by the usual methods, either in a lathe or by dipping, etc.; heat it over gas flame or spirit lamp, so that water will steam off it but not fizz, and then apply the chloride of antimony liquor with a piece of rag or pad attached to a piece of wood; when the metal has assumed an even color, polish by rubbing with a soft cloth perfectly clean and dry, and protect with a coat of clear lacquer. Should you prefer a darker color, use either of the following recipes: (1) To one part oxide of iron, or iron filings, add one part arsenic and 12 parts hydrochloric acid. Dissolve the oxide of iron or filings in the acid, then add the arsenic, strain and bottle for use. (2) One pint of strong vinegar, one ounce of sal-ammoniac, one-fourth ounce arsenic, one-half ounce alum; dissolve in the vinegar and bottle. These mixtures are to be applied in the same way as chloride of antimony, and, as you are doubtless aware, the ultimate shades may be varied by treating with various lacquers. In all cases, the work should be polished with a dry cloth immediately the desired color is obtained, and in the case of the two latter recipes, the work should be lacquered at once; but with the chloride of antimony, this is not essential.—*Ex.*

JAPANESE CRAFTSMEN.—The Japanese, like the Chinese, are fairly good craftsmen and content with low wages, which enables fairly well-made goods to be placed on the market at cheap rates. In Tokio alone there are nearly 100 boot factories, turning out a large quantity of work, and independently of these there are special factories for supplying the army and navy, and in the provinces several factories have been established. They are well fitted up, and for the most part are replete with the best American machines, which turn out good work and are easily managed by Chinese workmen. They export goods to China and Australia, where they are offered at very low prices. Some of the sole leather is American tanned, but there are also several native tanneries. The Germans will, perhaps, be the greatest sufferers by this new departure, as they have hitherto supplied the bulk of the shoes imported into Japan.

FIR TREE WOOL.—It is stated that excellent wool has been made from the fiber of the fir tree by means of electricity.

SCIENTIFIC PROGRESS.

Flame.

A New Theory of Its Electrical Propensities.

The electrical propensities of flame, remarks the *Indian Engineer*, have been the subject of much curious speculation and experimental investigation ever since those early days when Gilbert discovered that an electrified body, which is not a good conductor, may be readily discharged by passing it rapidly through the flame of a spirit lamp. Although it appeared that the flame carried off the electricity and dissipated it in the air, Gilbert afterward observed that it was sufficient to place an electrified body near a flame in order to deprive it of its charge. The fact is that a flame is a gas or vapor raised to a high temperature by the chemical processes of combustion, and hot gases are invariably good conductors of electricity; currents of very hot air are especially good conductors, and they act even better than metallic points in discharging a charged conductor.

Volta, the pioneer of galvanic electricity, showed that the process of combustion actually generated electricity, and this may be readily demonstrated by placing a piece of burning charcoal or a burning pastille, such as is used for fumigating purposes, in connection with the knob of an ordinary gold-leaf electroscope, when the leaves will instantly diverge.

The diamagnetism of flames was discovered by Bancelari, and Faraday also demonstrated that currents of hot-air smoke, and all kinds of flames are susceptible to the action of magnetic forces. Faraday discovered that not only will a flame rob a charged body of low conducting power of a charge imparted to it, but that it is capable of exercising a certain selective action; thus negative electrification is more easily discharged than positive. Further, flames which are strongly electrified with negative electricity are repelled from conductors, but when they are positively electrified, this is not the case.

The foregoing results represent the chief data regarding the electrical or magnetic character of flames, that have been accumulated up to within recent years. Very little has been so far deduced from these observations, but Faraday made his experiments the starting point for a series of important investigations into magnetism of gases.

Within more recent years, however, the electrical properties of flame have been studied in the light of a more complete knowledge. A year or two ago a valuable contribution to the subject of electricity of flame was made by Elster and Geitel, two German electricians. They observed that flame is strongly polarized in cross-section, and that an electrode in the air about the flame is always positive to one in the flame. It used to be thought that the polarization of flame was longitudinal, but it seems that this is only apparent and due to mismanagement of the electrodes.

The results of their experiments led Messrs. Geitel and Elster to deduce the following theory: By the process of combustion, *per se*, electricity is not produced in flame, but the flame gases and the air envelope have the property of exciting, like an electrolyte, metals or liquids in contact with them. To this electrolytic excitation is added thermoelectric excitation, which is due to the incandescent state of the electrodes. The amount and nature of the excitation is independent of the size of the flame and dependent on the nature, surface condition and glow of the electrodes, and on the nature of burning gases. Among other interesting facts, these scientists observed that the flame may be combined in series, just like galvanic elements, in such a way as to form a flame battery.

The theory which we have just briefly stated, which is the natural inference from Messrs. Geitel and Elster's investigations, has lately received unqualified support from Messrs. Magnus Maclean and Makita Goto, who, working by different methods and on entirely different lines, have arrived at similar results.

It was shown that the flame is negatively electrified, while the envelope of air immediately surrounding the flame is positively electrified. The potential at the middle line of the flame is nearly zero, and the surface of the maximum negative potential lies just inside the flame, while the surface of maximum positive potential lies at a distance of 2 mm. from the boundary of the flame. The maximum difference of potential between the two surfaces lies somewhere between 2½ and 3 volts. Similar results were obtained with other flames, but in case of glowing charcoal, the point of the platinum wire must be brought very close to it in order to obtain the indication of positive potential of the film of air surrounding it.

The magnitude of the electrification of air depends upon the part of the flame that is put to earth. Hence the maximum positive electrification is obtained when the most negative part of the flame is earthed, and vice versa.

Hot air from flame appears to have a different property from ordinary hot air; the different effects were obtained when a large red-hot soldering bolt was used. This was shown by passing the hot air between metal plates, such as unpolished zinc, and polished zinc, polished copper, platinum, etc., and observing the difference of potential in volts. These latest experiments are, without doubt, confirmatory in their results, and they thoroughly support the conclusions of

Messrs. Elster and Geitel. So far no attack has been made on the new theory, which may, therefore, be taken as granted.

CURIOUS ELECTRICAL PHENOMENA DEVELOPED BY ALUMINUM ELECTRODES.—In a paper by M. Nyrrenf, recently published in the *Journal de Physique*, the author states that in a voltmeter fitted with aluminum electrodes and charged with dilute acid, when traversed by an alternating current, hydrogen is given off at both electrodes. Where the oxygen escapes, or what it does, is not stated. Curious though this be, the phenomena displayed when mercury is substituted for one aluminum electrode, the other remaining, and the current is passed through distilled water, are still more remarkable. The author states that under these circumstances the current will pass in one direction only, and he therefore calls such an arrangement an "electro valve." This is not all; the current that does pass is in the reverse direction to that due to a mercury-aluminum couple, and it is notably diminished by the acidulation of the water even in a slight degree.

A GREAT BRIDGE.—The great steel bridge across the Columbia river at Vancouver will be a mammoth concern. It will be 6000 feet from the Washington to the Oregon shore; it will be double tracked with roadway on top for teams, and will be erected upon pneumatic piers. The pivotal pier, or draw pier, will support a draw which will give an opening of 200 feet space on either side for vessels to pass, and the span immediately south of the draw span will be 375 feet. Whole structure to be of steel, built 10 feet above the high water of 1876, and 40 feet above low water. On account of the sandy formation it will be necessary to go down 80 feet below low water to get a firm foundation. This gigantic structure will cost over \$4,000,000. It will be Jan. 1st, 1892, before the cars can pass over it. The company is pushing the bridge and also the road as fast as men and money and their present perfected plans will permit.

NEW USE FOR THE TELEPHONE.—It is said that the telephone is about to have a new application—that of foretelling storms. Another discovery has been made as to one of the properties of this means of transmitting sound. By placing two iron bars at seven or eight meters distance from each other, and then putting them in communication on one side by a copper wire covered with rubber and on the other side with a telephone, a storm can be predicted at least 12 hours ahead through a dead sound heard in the receiver. According as the storm advances the sound resembles the beating of hailstones against the windows. Every flash of lightning, and, of course, every clap of thunder that accompanies the storm produces a shock similar to that of the blow of a stone cast between the diaphragm and the instrument.

ARSENIC IN GLYCERIN.—As mentioned in a note in this journal a few weeks ago, Rikart has demonstrated the presence of arsenic in a large proportion of the samples of glycerin examined by him, even those sold as chemically pure. In a recent communication on the subject, in the *Pharmaceutische Zeitung*, he states that he has become convinced that the source of arsenic thus found lies in the sulphuric acid that is used for the decomposition of the fats in the stearin works, candle factories, etc., whence the crude glycerin is obtained, and that its presence is due to defective methods of purification on the part of the glycerin refiners. The subject is an important one and warrants further investigation.

ALTERNATING CURRENTS.—It appears that Dr. Edward Latum has recently completed some very remarkable experiments on the physiological effects of alternating currents. He finds that the danger of the current diminishes as the number of alternations per second is increased. Thus it took 20 times as strong a current to kill a dog when the alternations were 4500 per second as when they were 120 per second. When the alternations were 300 per second the current was only half as dangerous to life as when the alternations were 120.

STEEL RAILS AS PIT PROPS.—In consideration of the serious inroads which are being made on the timber of this country by the use of wooden props in mines, it is satisfactory to note that a patent has been taken out for a method of making steel rails into pit props and supports for collieries, mines, tunnels, bridges, etc. The rails are cut at their ends and snipshly framed together. In point of cost, it is claimed that this mode of propping compares favorably with other systems.

A NEW YORK INVENTOR has recently patented an appliance for preventing the disagreeable noise often proceeding from an arc lamp. The theory of the invention is that the rapid alternate heating and cooling of the gaseous matter forming the arc is responsible for the trouble, and the remedy proposed is to increase the number of alternations in the current until the rate of vibrations is so great as to exceed one's ability to hear them.

IODIFORM is being made in Germany by means of the electric current. An alcoholic solution of iodide of potassium traversed by a jet of carbonic acid is subjected to the electric current, and Iodoform is produced in shape of small yellow capsules.

GOOD HEALTH.

The Process of Digestion.

We condense the following article on the process of digestion from *Hall's Journal of Health*: The grinding process of food, so essential to its fitness to enter the stomach, is carried on by the teeth. Saliva is an aid to this breaking up. It moistens the food and makes a partial solution of the particles. If it were not for its presence, the mouth would be dry, and it would be very difficult to masticate the food. There is a continuous canal running completely through the body, which is more winding in its course than the most crooked stream. It is called the alimentary (food) canal. The solid food, broken up by the grinding mill, passes through the alimentary canal in a liquid form. This canal is about 23 feet long, has many subdivisions, and is lined throughout with mucous membrane, which is full of blood vessels and secreting glands. The secretions from these glands dissolve the food, and the blood vessels, which are tributaries to the canal, absorb the nourishment from the food solution as fast as it is formed, and convey it to the tissues of the different organs of the body. In the walls of this canal is a muscular layer which causes the canal to contract around the particles of food, thus forcing it gradually along its whole length.

Opening into the mouth are the openings of three sets of salivary glands. When the mouth is at rest, the salivary glands secrete a small but constant amount of fluid, and when the jaws are in motion the flow is rapid. The total amount of saliva secreted in one day is about two and a half pints. The same is true of the other glands, which secrete more abundantly when there is work for them than when in a state of idleness.

The muscular coat of the stomach is quite complicated. The contractions of this muscular layer produce a varied motion to the contents of the stomach. The food is caused to pass along the sides of the stomach and back through the center, thus bringing all particles of food into close action with the gastric juice. By this provision in the structure of this organ an important function is established. When the stomach is empty it is in a state of collapse, and its walls are in opposition. When filled with food it is distended in the form of a sack or bag about one foot long by six inches across. The liquid solution of the food as made in the stomach, is called chyme. The inner wall of the stomach, when it is empty, is thrown into rough ridges, but when it is distended the wall is stretched smooth and shows little openings on its surface. These openings are small depressions from 1-100th to 1-200 of an inch in diameter. In the sides and bottom of these depressions are minute orifices, which are the mouths of the gastric glands. At the upper and larger portion of the stomach is the cardiac valve, and at the smaller and lower end is the pyloric valve. An interesting fact about the pyloric valve is that the side toward the interior of the stomach is covered with mucous membrane similar to that lining the stomach, while the other side is covered with villi, which project from the surface, and are about half a line in length.

The gastric juice has been found to be a colorless liquid, or of an amber hue. Its chief elements are water 975 parts, free acid 4.78 parts, and pepsin 15 parts. Other elements in minute quantities are potassium, lime, ammonium, magnesium and iron. The pepsin is precipitated from the gastric juice if some of the bile flows back into the stomach through the pyloric orifice, instead of passing along the intestine, as it should. Digestion is stopped if either the acid or the pepsin is absent, hence both must be present in solution for the gastric juice to do its work efficiently.

If one has dyspepsia, either there is bile present in the stomach, or the gastric juice has lost its acidity. The chief characteristic of the gastric juice is that it digests albuminous substances. Examples of this work are the dissolving of the white of an egg, the making of liquid of the casein of cheese, while the oily particles are set free. The stomach digests certain portions of the food, the small intestine a certain part, and the large intestine carries away the waste materials. Albumen may be present in many varieties of food; in meats, grains, fruit and in vegetables. Boiling a vegetable greatly aids the process of digestion.

The reason why the gastric juice does not act upon and digest the stomach itself is because the gastric juice is acid, while the blood is alkaline, and as the walls of the stomach are well supplied with blood vessels, the gastric juice cannot react on the stomach, because an alkali and an acid will neutralize each other.

Now we have the stomach occupied with gastric juice and the albumen of food in solution, also the oily matter and starch, apart by themselves and mingled with the other liquid matter. The pyloric valve opens and all of the contents of the stomach pass into the intestine. The pyloric valve closes and the stomach quiets down. Opening into the small intestine are two or more ducts or tubes. One of these ducts introduces the bile from the liver into the small intestine. A little lower down are two openings, the ends of the pancreatic ducts, which permit the flow of the pancreatic juice into the intestine. The important element of the pancreatic juice is the pancreatine. This is capable of digesting the oils and fats, and of

changing the starch to sugar. The bile is present here, and it is supposed that it aids to a great extent as a cathartic in washing out the bowels. The pancreatic juice makes a white, milky emulsion of the fats.

We now have a mixed solution in the small intestine, which is of small calibre and about 20 feet long. On the inner surface are millions of villi, which project into the cavity of the intestine. These villi are traversed by minute blood vessels.

The albuminous emulsion of fats and the sugar are absorbed by osmosis directly into the blood in the blood vessels of the villi. Osmosis means the passing of a liquid through the tissue. The gastric juice is also absorbed from the intestine by these villi, and is secreted again in the glands of the stomach as the albumen is taken up from the gastric juice by the blood. Thus we get a circulation of this gastric juice. It is secreted in the stomach, dissolves albumen and passes into the small intestine, is absorbed by the blood vessels and is again taken up by the gastric glands, where it is ready to be secreted in the stomach again when there is a demand for it.

After the albumen, the fat emulsion and the sugar have been absorbed from the small intestine the debris, in the form of vegetable tissues, undigested animal tissues and the waste from the process of digestion, is passed on to the large intestine.

Food should be properly cooked, and slowly and thoroughly masticated. After a hearty meal the best thing to do is to sit quietly back in an easy chair and doze, while digestion is going on, or for a time at least, until digestion is well under way.

The dinner should come at that part of the day when the most time can be given to it.

Nitrogen and carbon are the two principal ingredients of food. Nitrogen supplies the waste tissues and carbon furnishes heat.

Plants and vegetables inhale carbonic acid gas and exhale oxygen.

Animals inhale oxygen and exhale carbonic acid gas.

Man is no exception to the rule.

USEFUL INFORMATION.

COMPRESSED COAL IN FRANCE.—Compressed coal is coming largely into use in France. It is reported that there is hardly a torpedo boat belonging to France in which the compressed coal dust is not used, and it is consumed in the battle ships wherever possible. These briquettes are generally composed of a mixture of from 8 to 9 per cent of pitch, with 92 to 91 per cent of coal dust. In the most improved machines the coal dust and the pitch are shoveled into a hopper, and it is not touched again until it is automatically stacked in the yard outside the engine-room. The materials are consolidated by means of a mixing apparatus into which steam is admitted. A form of coal which, by itself, is almost useless for burning, is thus converted into a really serviceable fuel, that, as regards cheapness, may be made to enter into successful competition with the best steam coal. More persistent efforts should be made to utilize the mountains of coal waste which are so fast accumulating in this country.

TO DISTINGUISH A GENUINE DIAMOND.—It is said that an expert is no longer required to tell whether a diamond is genuine or not. The test is simple and can be made in any place and in a moment. All you need is a piece of paper and a lead pencil. With the latter make a small dot on the paper, then look at it through the diamond. If you can see but one dot you can depend upon it that the stone is genuine, but if the mark is scattered, or shows more than one, you will be perfectly safe in refusing to pay ten cents for a stone that may be offered you at \$500. Of course a diamond to be subjected to such an examination must either be without its setting, or so mounted that the light will pass through it perpendicularly.

TESTING STEEL TIRES.—The Pennsylvania railroad is engaged in experiments to determine the relative wearing qualities of hard and soft locomotive tires. Dr. Dudley, the chemist of the company, who has charge of the tests, selected steel containing seven per cent of carbon for the hard tires and three per cent for the soft ones. Before being put on the wheels of the locomotive, each tire was carefully marked and measured, and a hard tire and a soft tire was put on each axle, so that a perfectly even distribution of the two kinds of steel was secured. The engines have been in use for several months, and a record is kept of the wear.

BOOTS WITH STONE SOLES, which are said to be very flexible and almost indestructible, are the idea of a German inventor. A thin leather sole is used, a paste of quartz sand and waterproof glue being spread on it.

The average weight of a crowd of men standing as closely together as possible is 34 pounds per superficial foot.

COPPER AND INDIA RUBBER.—It is stated that copper piping when hot has an injurious effect upon any India rubber tubing with which it may come in contact.

The metal in a 5-cent nickel piece is worth about half a cent, and 15 cents will purchase copper enough to make \$2 worth of cents.

ELECTRICITY.

ECONOMIZING IN ELECTRIC LIGHTING.—The filament of the incandescent electric lamp deteriorates after a time, thus causing a diminution of the candle-power, and finally its displacement. To remedy this, two Germans have invented two processes which are now attracting the notice of electricians. The first process consists in the use of osmium, which is deposited on the osmium filament either by electrolysis or by a chemical method. The inventor claims that the melting point of the osmium is so high as to resist the temperature of the electrical current and greatly increase the life of the filament. The other inventor employs the nitrides of silicon or boron for the same purpose. The filament is heated to incandescence in an atmosphere of volatile nitrogen compounds, when the heat reduces them and forms solid nitrides of silicon, which are found to be deposited with great uniformity over the surface of the filament. Another invention relates to utilizing or mending the filaments after they have become useless. The old filament is removed by a special process, with the exception of a small piece which is allowed to remain on the platinum supports. A new filament is then introduced and joined to the two ends of the old filament by another special process. Thus patched the lamp is as good as when new.

AN IMPROVED UNDERGROUND ELECTRIC PROPELLOR.—A new method of applying an electric current to underground wires has been discovered by Western parties. The wire is placed in a conduit somewhat smaller, but much similar in appearance to the cable conduit, and the car is fed by a trolley underneath the car. Hitherto the current has escaped from a bare trolley underground wire in a damp conduit, making it impossible to get the power of the electricity for but a short distance from the dynamo, but by this new system a section of small wire 25 miles away may be charged at practically the same expense as one a block distant. A company backed by half a million dollars has been organized at Tacoma, Wash., and proposes to push the thing to the utmost.

SUBMARINE CABLES.—There are at present 26 submarine cable companies, the combined capital of which is \$200,000,000. Their revenues, including subsidies, amounts to \$16,020,300, their reserves and sinking funds to \$18,050,000, and their dividends are from 1 to 14½ per cent. The receipts from the Atlantic cables alone amount to about \$4,000,000 annually. The number of cables laid down throughout the world is 1045, of which 798 belong to Governments and 247 to private companies. The total length of these cables is 120,070 nautical miles, of which 107,546 are owned by private telegraph companies, nearly all British; the remainder, or 12,524 miles, are owned by Governments.

ELECTRICITY AS AN AID TO BURGLARS.—An expert, not long ago, says a contemporary, chagrined the treasury officials by opening the vaults without a knowledge of the combinations. Now here is a method by which any ordinary burglar with the slightest knowledge of electricity can "crack" the strongest safe built, with dispatch and without noise. Let him connect the safe with one pole of an electric machine, and putting a carbon point on the other pole, place it against the safe at the spot desired to work upon. In a few minutes the action of the current will soften the iron or steel to such an extent that it will be comparatively easy to cut. If the burglar is an electrician, he can utilize the electric light wire for the purpose.

CROSS COUNTRY ELECTRIC RAILROAD.—The experiments which have attended city passenger traffic have succeeded so well that efforts are now to be made to apply electric propulsion to cross country roads. The first experiment is to be made in Minnesota, between Stillwater and St. Paul, 25 miles. It is intended to have the road in operation for both freight and passenger traffic by October 1st. It is said that power is to be obtained from Niagara Falls for operating an electric railway which Rochester capitalists propose to build. The road is to be 80 miles in length.

METALS BY ELECTROLYSIS.—It may not be generally known, says a London electrician, but it is important that it should be, that metals deposited by electrolysis do not adhere well, if at all, to their kind; thus electro-deposited gold will not adhere to gold, silver to silver, nickel to nickel, nor copper to copper, and so on.

THE MANIFOLD USES OF ELECTRICITY.—Electric motors have been applied to upward of 140 different uses, and the number is still increasing. The sizes of the motors include those of from a mere fraction of a horse power up to one of 5000-horse power, which is in operation near London, Eng.

ELECTRICAL FIREWORKS.—An electrician who has made a specialty of spectacular electricity says the day is not far off when electrical fireworks will supersede those now used.

AN EXPERT ELECTRICIAN insists that an electric train, making 125 miles an hour, would require 7000 feet—over one mile—in which to come to a standstill.

ENGINEERING NOTES.

Unsinkable Ships.

With the advancement that is being made in every other line of industrial and commercial development, there has come a demand for improvements in the construction of vessels and ships, which are becoming more and more an important factor in our commercial relations, not only among ourselves, but with foreign nations. Many improvements have been made which have made modern ocean travel more safe, speedy and reliable, but so far no feasible plan has been suggested by which a vessel would be made practically unsinkable. In this, as in many other instances and improvements, it has remained for Yankee invention and ingenuity to work out and demonstrate such a plan.

Capt. Meacom of Chelsea, Mass., has recently patented an invention which promises to be of great importance in the future construction of ocean-going vessels, and his invention is briefly described as follows:

"He has developed a double-hulled ship with compartments so arranged and constructed that it supplies a mathematical certainty against sinking. Between the outer and inner shells of his vessel is a series of longitudinal compartments, to be filled and emptied with water by the vessel's pumps, for ballast. Above this section on either side, and rising to the full height of the vessel's sides, is a series of chambers filled with small air-tight tanks, their capacity being figured in excess of the known displacement of the ship and cargo. Thus a cubic foot of air has a perfect supporting capacity for a known weight. If the supply of air in these tanks is 25 per cent above that required by the formula, nothing short of fragmentary destruction could sink a vessel. Any probable collision, the penetration of a shot or the explosion of a torpedo would injure only a small proportion of the air-tanks, and the rest would easily and safely perform their work."

A vessel thus equipped would be practically non-sinkable. It would, of course, have a less carrying capacity; but in passenger steamers and warships, where safety is especially desired, the sacrifice may well be made.

CANAL BUILDING seems to have entered upon a new phase of activity. Scarcely a month passes that does not bring out some new canal enterprise or revive an old one. Ship canals appear to take the lead. The present coast defense discussion appears to have revived the talk of canals between Philadelphia, Baltimore and the sea coast nearly as much in the light of war measures as for greater commercial facilities. A New Jersey canal of considerable length is also discussed. Scotch capitalists are thinking over a plan to dig a canal through the land of oaks, joining the Atlantic and the North sea. Like nearly every engineering project of recent years, the scheme is entirely practicable, provided enough money can be secured. Often, however, the enthusiastic support of such plans comes from men who see in their success a furtherance of their own financial well-being rather than a return to the investors. A long canal necessarily buys a great deal of material and employs a large number of men.

SAN RAFAEL CANAL.—A canal is being constructed from tide water to the broadgauge depot in San Rafael. On each side of the canal will be a levee five feet in height above the marsh and 30 feet in width. At the broadgauge depot the width of the canal will be 90 feet, allowing ample room for echonere to turn. For the rest of the distance the canal will be 52 feet wide. The bay shore is to be protected by a levee four feet above high water and 40 feet wide, the surface to be used as a roadway. The length of the levee will be about 4 miles, starting at the broadgauge depot and terminating at a point near the high bluff at Point San Quentin. The canal will be about three miles long, about one-third of which length has already been completed.

RAPID RAILWAY TRANSIT.—It is said that a company has been organized, with a capital stock of two and a half million dollars, to put to a practical test the Weems electrical railway system. This system is the result of the experiments on high speeds by E. T. Crohey, who was the first engineer to attach a high-speed motor to the axle of a car, and at a recent test the incredible speed of 130 miles per hour was obtained from a car ten feet long and two feet high upon a two-foot gauge track. The car was pointed to lessen the air resistance and contained nothing with the exception of a set of instruments that showed a much less resistance from air than had been supposed.

A GERMAN engineer has devised a new method for fixing a foundation under water. By means of a powerful blast of compressed air he drives powdered cement down into the sand or mud at the bottom of a stream. The action of the water immediately fixes the cement, and it becomes like solid rock.

THE Hudson River Tunnel is within about 3400 feet of the 5400 feet necessary for completion and is progressing at the rate of ten feet a day.

Passing Events.

Among the notable events of the past week was the fine shower that visited this section of the State on Wednesday morning. The rain continued for about two hours, falling part of the time quite heavily. This is an occurrence not usual so late in the season. While this rain damaged somewhat the hay in process of curing, also the strawberries slightly, it helped the grass, everywhere still green, refreshed the gardens and lawns, benefiting at the same time the ripening fruits and the later maturing crops of grain. As a means of laying the dust, this shower was welcomed by the denizens of San Francisco, it having accomplished a feat that our municipal authorities never so much as undertake.

The preliminary work of the World's Fair seems to be making satisfactory progress. The erection of the big buildings is about to be commenced, and many foreign Governments have signified their intention to take part in the great show.

Our local labor troubles, instead of meeting with abatement, as hoped for earlier in the year, appear to be multiplying as the season advances, causing much loss to both employers and workmen, as well as serious incon-

venience to many other classes of the community. Many branches of business are suffering severely from this cause, which, if continued much longer, will tell with damaging effect on all our industries, driving away trade and checking building operations and improvements of every kind. It is a pity some plan cannot be hit upon for obviating these troubles or insuring their ready adjustment when they do occur.

The Future.

Sir Charles Dilke, in a recently published work in two volumes, entitled "The Problems of Great Britain," expresses the belief that in the future the world will be practically divided between the Anglo-Saxon, the Russian and the Chinese. If the present rate of increase both in numbers and wealth is kept up, the French and German nations will appear as plumes beside the all-conquering Anglo-Saxon. The German surplus of population has largely overflowed into boundless America, and to all intents and purposes becomes Anglo-Saxon. How many millions of people there are in the United States whose names alone indicate their Gallic or Teutonic origin. How many more in Great Britain and her provinces. Had Sir Charles Dilke's prescience reached far enough, might he not have made the statement that the Anglo-Saxon is the coming race? Russia, it is true, while old in years, is young in progress. Her awakening is that of a young athlete. Her power is physical. Something more is needed if she is to keep step with the Anglo-Saxon and rule the world or divide it into three parts; yet Sir Charles Dilke's predictions may be verified if Russia is content to work out the possibilities of her now practically endless domain. The autocratic rule of the house of Romanoff will be modified before the next generation has passed away. Then, and not before, Russia's future greatness or weakness may be foretold.

We may fairly suppose that Sir Charles Dilke sees the Chinese through other lights than we who know them as a sort of human teredo.

China has vast areas of unoccupied territory which will in time be occupied, if not by Chinese, perhaps by Russians. China, unlike other nations, loses nothing to the Anglo-Saxon through emigration; wherever a Chinese emigrant is found he is a Chinaman. If the great wall of China is ever rebuilt, it will be done by the rest of the world; its purpose will be to keep the Chinese in and a thorough job will be made of it.

The World's Want is More Money.

Mr. Goschen, Chancellor of the British Exchequer, advises the issue by that Government of one-pound notes, and also of 20-shilling notes secured by silver. No bank of England note has yet been issued for a less sum than five pounds; both these propositions are a new departure in British finance. It shows that Mr. Goschen, at least, fully realizes the fact that the increase of money has by no means kept pace with the world's requirements, and that something besides gold must be used as a money base. It shows also that silver will be used to supply this basis for more money.

Money-lenders and all who trade in money and prosper best when money is tight and "times are hard," have and will continue to oppose an increase of circulating money because it suits their present selfish purposes.

The farmer, the miner, the manufacturer—those who need money to carry on the industries and commerce of the world and to develop new industries—need money at reasonable rates of interest. They do not so much exercise themselves about the security back of this money, if only it have the good faith of the Government issuing it, though all agree that silver, which has served so long and well, properly supplies the want. The gold advocates, or rather the opponents of more money in this country, know that if any other basis than gold is used to increase the circulating medium it will be silver, therefore their whole effort has been directed against silver. They have counted on England's financial policy as backing of the first order, and it would seem as if this proposition of Mr. Goschen must be a knock-out blow for them.

We have no need of land notes or any other form of money in this country than gold and

silver if we fully utilize our resources of these metals, and there will be enough for England as well.

For the Benefit of the Miners and Their Friends.

Notwithstanding more effective means for preventing accidents in mines are all the while being devised, the occurrence of this class of casualties seems to be as frequent as ever. Relatively this is not perhaps the case, there being, of course, a constant increase in the number of men employed at this business. But even in this view of the subject these accidents are all too frequent, suggesting that suitable measures be taken for mitigating their consequences as far as may be. Since we cannot prevent the miner from being disabled and sometimes killed outright, we should devise some plan whereby those dependent on his labor for support would not, in case of disaster, be left wholly destitute.

A bill having been introduced into the British House of Commons designed to make the insurance of the Scottish miners compulsory, the expediency of extending this rule to the English miners as well is now being discussed in that branch of Parliament. This bill provides that the owner or lessee of the mine shall contribute a small sum on its annual output, and the miners themselves from two to four cents of their weekly earnings, to constitute a fund, out of which a weekly allowance shall be made for the support of his family in the event of the miner being through accident killed or disabled while at work. For enforcing the law and looking after this fund a board of management is appointed, the miners, mine owners and the inspector of mines for the district being represented on this board.

To what extent any such arrangement would, in this country, be practicable or desirable, becomes a question, the conditions here being so unlike those that prevail in older countries. In the latter the miners are less migratory than they are apt to be with us, the most of them following no other parent, and spending their lives in the district where they are born. Being so permanent and bound to the neighborhood by the ties of family and kindred, these men would be much more likely to consent to the payment of a small weekly stipend for the purpose named, than would miners in the United States, who, more widely scattered, and drifting from place to place, could have no surety that the benefits of this fund would be extended to them in case of accident. It was the unsettled habits of this class that prevented their ever combining into a stable and effective union, such as has been possible with most other guilds in this country.

But this is an evil that steadily tends to correct itself. Our miners, even on this coast, where this migratory spirit has been most manifest, are every year becoming more and more fixed, accordingly as the self-employing fields have narrowed, and the life of the prospector held out fewer and fewer temptations. It might, therefore, be practicable to frame a law calculated to subserve the end here contemplated, and the provisions of which would be acceptable to those intended to be benefited thereby. It would, at all events, be well for the newspaper press to discuss this matter, in the hope that such suitable plan be evolved as would, before the next session of our State Legislature, commend itself to both the mining and the general public.

ORE rates from Wood River have been fixed at \$8 a ton to Salt Lake, \$11 to Denver, \$12 to Pueblo, \$14 to Kansas City, \$13 to Omaha and Council Bluffs, and \$14 to Leadville. These rates went into effect May 20th, and should give a fresh impetus to the extraction and shipment of ores from Wood River. No place more abundant in rich silver ores, and by giving to the miners rates that will enable them to ship medium as well as high-grade ores, vast quantities would soon be shipped and both the roads and the miners reap a harvest beyond anything yet experienced in this State.

THE works at the new smelter at Pioche are beginning to assume an air of business, and from present appearances it will be but a short time before the million begins to make its appearance.

THE managers of the World's Fair are still trying to cut wages—perhaps on the principle of the more wages the less swag.

Diamonds.

Where they Occur and How to Search for Them.

Frequent inquiries are being made by placer miners and diamond prospectors, for some simple way by which, without the possibility of mistake, they can tell when they find diamonds in the working of their placers. We have looked over most of the books on the subject of precious stones, but cannot find in any one of them plain directions for that purpose. We often hear of stones, supposed to be diamonds, being sent to London, Paris, and other places for determination denoting that there is much attention being paid to this matter. Knowing that one of our old correspondents, Melville Attwood, F. G. S., had been in the diamond mines of Brazil, we asked him if he could furnish us with the desired information, which he, having kindly consented to do, will be found embodied in the following article:

"I think," says Mr. Attwood, "that the gold and diamond placers of Brazil, like those of California, may properly be divided into three classes:

"1st. The surface washings and the Ravine diggings, which have derived their gold principally from the degradation or breaking up by atmospheric and aqueous agencies of the outcrops of the auriferous veins. The gold found in these placers is mostly angular, with pieces of quartz adhering to it. This class, to a certain extent, has been the most important of the three, as nearly all our richest quartz veins were discovered by working them. For instance, in the Grace Valley district, at Rhode Island Ravine diggings, the first gold vein was uncovered—the Gold Hill. Then the Boston Ravine diggings, the Massachusetts Hill mines, the Allison Ranch diggings, the Allison Ranch mine, the Lamarque diggings, near the north branch of Wolf creek, which uncovered the Enreka, Idaho, etc.

"2d class consists of the recent river-beds, from which the water has been diverted, and the present river-beds. In this class most of the Brazilian diamonds are met with.

"3d class, the ancient river-beds in which diamonds are also found.

"The Brazilian miners distinguish the various diamond placers by the following names: Genpiara, an alluvial deposit whose surface shows it to be the unmined bed of a stream or river. Burgalhao are small fragments of rock, bestrewn the surface of the ground. Casalho, fragments and pebbles of quartz, or rock and sand mixed with clay, forming the bed of a river. Takoa Carza, which consists of the above materials cemented together, forming a conglomerate mass.

"The diamond prospector's outfit, should consist of a light pick, a shovel, and two riddles, one having three-fourths of an inch apertures and 18 inches in diameter, the other having eight holes to the linear inch; a miner's wallet, which is a bag four feet eight inches long by 18 inches wide, with an opening in the middle. It can be carried over the shoulder or used as a saddle-bag. With it a miner can pick 40 pounds of gravel or more for a long distance. A tub for washing the gravel in. This may be got by cutting a wire or barrel in two. A rubber bath-tub will also answer the purpose. A piece of rubber cloth, to be used for sorting the gravel on. A watchmaker's lens of two powers, fitted into a spectacle frame. A placer miner's scale of hardness, consisting of fragments of diamonds, sapphires and quartz, mounted at the end of a penoil. This outfit, with the scale of hardness, can be obtained of John Taylor & Co., San Francisco. The scale of hardness can easily be made, by taking the rubber out from the end of the penoil and filling the space with lapidary's cement, which melts at a very low temperature. Over a small spirit-lamp, warm the fragments of diamonds or sapphires, and while hot, insert them into the cement. By wetting the fingers and rubbing it, the cement can be molded into any shape desirable, and when cold, it will be as firm as if soldered.

"The sample of gravel to be examined must be first put into the coarse riddle and that fastened above the finer one. Then immerse both riddles into a tub of water, and with a half-rotary motion, wash all the fine gravel into the lower one, the dirt and sand passing through into the tub. Then throw away what was collected in the coarse riddle, unfasten it

from the finer one, immerse the latter in the tub of water, and use a jiggling motion till all the heavier portions of the gravel have settled at the bottom. Continue the jiggling, and by raising the riddle a little at one side, you can get all the gravel to the opposite one. Then, with a very quick motion, turn the contents on to the sorting cloth or board, which should be placed near the tub. The heaviest gravel will then be at the top, and can easily be examined and tested; by taking the pencil with the fragment of diamond mounted at the end of it, and pressing lightly, try to scratch the suspected stone, at the same time looking at it through the lens. If no mark or scratch is found upon it, it must be a diamond, no matter what the shape or color.

"The fragments of diamond may be protected from injury by the metal covering used to cover the sharpened end of pencils. In Brazil, as yet, no mines have been discovered like those in South Africa, such as Kimberley, De Beers, Du Toit's Pan, and Bultfontein, where the diamond's may be said to be found in place."

Mr. E. I. Dunn, in a paper read before the London Geological Society on the African diamond mines, says: "That the old mines are 'volcanic pipes,' and that they have burst through these carbonaceous shales, is evident. Is it not reasonable to infer that the carbon, indispensable in one form or another to the formation of the diamond, was supplied by these shales?"

I think the chances are good that we may yet find in California one of these "volcanic pipes."

In the PRESS of June 25, 1887, and July 9, 1887, will be found a full account of the African diamond mines, with plans and sections of the same.

Wolf's Patent Safety Lamp for Mining Purposes.

On this page we represent the different parts of a miner's safety lamp, very useful in nearly all kinds of underground mining, more particularly, as the use of benzine is a better light, of uniform intensity and does not deposit any lamp black to clog the lamp.

Fig. 1, represents a benzine safety lamp for mining purposes, provided with a device for lighting the same, while it is closed, and with a magnet locking contrivance. Figs. 2 and 3, illustrate the lighting device in full size. It has proved so advantageous, that no lamps are now ordered unless provided with such a lighting device. It is provided with a peculiar locking contrivance, impossible to open, except by means of a particular magnet. Fig. 4, represents such a locking device, located in a case or shell, attached to the screw ring of the lamp.

Fig. 5, shows the best and latest arrangement of the device. Fig. 6, by a scale of, say one-third of the natural size, a lamp for ascertaining the state of the atmosphere in drifts. Fig. 7, shows a signal lamp used in mining surveys. Fig. 8, shows a lamp similar to Fig. 1, of larger size, and with quadruple tubular burner, the light being more intense, and suited to large spaces. Fig. 9, represents an apparatus for testing the above-described safety lamp. Fig. 10, represents an apparatus for filling the safety lamps without danger. Fig. 11, is the magnet to be used to open the lamp. Fig. 9, representing the testing apparatus, is probably the most important, as few safety lamps are made to show absolute safety until placed in use; when it may be too late, as any disastrous accident, resulting from the use of a defective lamp, could have been prevented by using the test, which rejects all but perfect lamps. The operation, a chemical and mechanical one, is a too complicated one to be fully described in this article.

St. Louis, Mo., says the *Danver Industry*, will receive five million dollars this year in dividends from mines of gold and silver. Of this handsome net income, four millions will be derived from the Granite Mountain, Bimetellio and St. Joseph lodes. This is a good showing for a city that is not known as a mining town. It is probable that the mine-owners of St. Louis have made of it a side issue, only investing some of their surplus, while prosecuting some other branch of business, to which they give their personal attention.

The men who are producing these results, however, must be mining men, who are not only miners but business men. It is a well

demonstrated fact that practical success in mining involves the employment of business ability along with a knowledge of the detail of practical mining. The mining industry in St. Louis should be favorably regarded.

THE UNITY MINING CO.—The Unity Gold and Silver Mining Co. has been lately incorporated in this city to work the Skyblue,

ELECTRICITY TO HOIST COAL.—Another practical step in advance in the use of electricity has been made at the Black Diamond mine. An electric hoisting machine has been placed at the top of a slope 450 feet in length, for the purpose of hoisting coal, the top of the slope being 3100 feet from the mouth of the mine. The generator which supplies electricity to the motor attached to the hoist has a capacity of

WOLF'S PATENT SAFETY LAMP.

Crossbow and Daisy Dean mines, located about one-half mile above Middle Creek, on the Sacramento River, Shasta county. The directors of the company for the ensuing year are W. D. Biegle, A. R. Becker, Arnold Becker, P. J. Bughee and J. A. Bouk. The company has already commenced work on the mines, designing to develop them to their fullest extent. Negotiations are now under way, for a plant of the most improved machinery and processes, such as are now used in Australia. It is thought that the introduction of these new methods, in handling the ores, will be of great benefit to the miners of Shasta county.

120 horse-power, and is located at the mouth of the mine, while the motor is capable of exerting 80 horse-power when needed. Yesterday, on a test, 12,000 pounds of coal were hoisted at one trip up the slope in one and one-half minutes. The plant was manufactured and installed by the Electro Engineering Company of San Francisco, under the supervision of Prof. Keith, the inventor, and is pronounced a thorough success. It is claimed that it makes practicable the working of many coal and other mines which could not be so cheaply and effectively worked by the usual methods of steam or pneumatic transmission of power.

The Deadly Open Car.

Certain Boston officials, claiming to act in the interests of the public health, have sued out an injunction to restrain the street railroad companies from running open cars into the suburban districts. And what think you, reader, is the reason assigned for this restraining measure? Simply this, and nothing more: If these open cars are allowed to be run, people riding on them will through such exposure to the open air, be liable to take cold and thus invite an attack of the grippe, and ailments of a like kind! This is considerate but exceedingly stupid, the only way whereby people can escape these bronchial troubles being through outdoor exposure, to fortify themselves against them.

Who are the people that suffer most from maladies of this kind? Always those who live in unventilated rooms, ride in closed cars and in other ways seek to protect themselves from the least breath of air. The street gamin, with his bare throat, never has the grippe, nor are outdoor laborers of any kind apt to suffer from this or similar complaints. Wind alone hurts no one, if warmly dressed.

The passenger who thus protected cannot, in fair weather, ride on an open car, however strong the wind, had better make a will and order a coffin. And here it may be proper to observe that on this coast the common mistake is made of wearing too warm underclothing. As a rule, when additional clothing is required, it should be in the form of an overcoat or other outer garment. Wearing constantly thick drawers and undershirt, as we usually do here in California, is exceedingly debilitating, the system through this practice becoming so tender that colds are contracted on the least exposure. No hardy or long-lived race need be looked for if this habit of bundling up the person and avoiding the fresh air is to be adhered to.

The fact is, air starvation has killed more of the human race than any other form of famine. Shutting out what is called a draught has delivered over to death more victims than war or pestilence. Through lack of ventilation we deliberately convert our houses and schools, our courts and workshops, and even our places of amusement and worship into veritable "Black Holes," spending often a good deal of money to thoroughly exclude the life-giving element. Our great hotels are prison pens, almost as deadly as Andersonville or Libby, so effectually is the pure air shut out and the vile air shut in.

We trust the denizens of the "Hub," following the example of the people on this side, will insist on having enough open street cars to accommodate the advocates of free air, with always a compartment for the over delicate and wheezy, putting on an inclosed but properly ventilated car for the use of all in stormy weather.

The Tariff on Lead Ores.

If Colonel R. M. Moore is correctly reported in the *Eagle Pass Guide*, he is entitled to the compliment of having expressed more good sense than any other official on this subject. That paper says: "Colonel R. M. Moore, special agent of the United States Treasury Department, has just returned from an extensive survey of Mexican mines, and his observations have convinced him of the needlessness of attempting to prohibit the mixing of ores unless by the total prohibition of their importation. Ores of many different grades and classes are often found in the same mine, in the same shaft, or even in the same vein. Whenever these ores are mined, they are so far concentrated—separated from the surrounding or intermixed valueless rock. Thus the literal construction of the terms of the rule would exclude all Mexican ores from importation, while it is practically impossible to agree upon the amount of latitude to be allowed in construing them. Under these circumstances, Col. Moore thinks the only rational remedy lies in such a change in the laws as will do away with the attempted classification of ores, and levy upon all lead in the ore the same tax, regardless of the classification of ores or the relative quantity of the metal."

If a man could live a thousand years he would probably spend the last 50 fretting over what he might have done in the previous wasted time.

DAVIS'S Bricks, Tiles, and Terra Cotta

RECENTLY PUBLISHED.

A NEW EDITION.

A PRACTICAL TREATISE ON THE MANUFACTURE OF BRICKS, TILES, TERRA-COTTA, ETC., including Hand-Made, Dry Clay, Tempered Clay, Soft Mud, and Stiff Clay Bricks, also Front, Hand Pressed, Steam Pressed, Re-Pressed, Ornamentally Shaped and Enamelled Bricks, Drain Tiles, Straight and Curved Sewer and Water Pipes, Fire Clays, Fire Bricks, Glass Pots, Terra-Cotta, Roofing Tiles, Flooring Tiles, Art Tiles, Mosaic Tiles, and Imitation of Intarsia or Inlaid Surfaces, embracing every Important Product of Clay employed in Architecture, Engineering, the Blast Furnace, for Retorts, etc., with a History and the Actual Processes in Handling, Disintegrating, Tempering and Molding the Clay into the Shape, Drying Naturally and Artificially, Setting, Burning with Coal, Natural Gas and Crude Oil Fuels, Enameling in Polychrome Colors, Composition and Application of Glazes, etc., including Full Detailed Descriptions of the Most Modern Machinery, Tools, Kilns, and Kiln Roofs used. By Charles Thomas Davis. Second Edition, Thoroughly Revised. Illustrated by 217 engravings, 501 pages. 8vn.

Price \$5.00, by mail, free of postage to any address in the world.

CONTENTS.—CHAPTER I. The History of Bricks. II. General Remarks concerning Bricks, their Size, Strength, and other qualities. Ornamental Bricks. Architectural Terra-Cotta. Blue Bricks. Saltpetre Exudations upon Brick Work. III. Enameling, Glazing, and Ornamenting Bricks and Tiles. Earthenware, etc. IV. Selecting Clays for Various Kinds of Bricks—The Different Varieties of Clay—The Characteristics, Qualities and Localities—How to Color Bricks Red—Kaolin, Terra Cotta Clays. Fire Clays—Exploring, Digging and Marketing Fire Clays—Washing Clays. V. Making and Burning a Kiln of Hand-Made Bricks. VI. Manufacture of Dry Clay Bricks. VII. The Manufacture of Tempered Clay Bricks, including a description of the most Modern Machinery Employed. VIII. Kilns. IX. The Manufacture of Pressed and Ornamental Bricks. X. The Manufacture of Fire Bricks. XI. The Manufacture of Drain Tiles. XII. The Manufacture of Sewer Pipes. XIII. The Manufacture of Roofing Tiles. XIV. The Manufacture of Architectural Terra-Cotta. XV. Ornamental Tiles, etc. Index.

A circular of 6 pages quarto, giving the full Table of Contents of this important Book, with specimens of the illustrations, will be sent free of postage to any one in any part of the world who will furnish his address.

HENRY CAREY BAIRD & CO.

INDUSTRIAL PUBLISHERS, BOOKSELLERS AND IMPORTERS,
810 Walnut St., Philadelphia, Pa., U. S. A.

GREAT REDUCTION!

BATTERY SCREENS.

Best and Cheapest in America.

PERFORATED SHEET METAL

For Flour and Rice Mills, Grain Separators, Revolving and Shot Screens, Stamp Batteries and all kinds of Mining and Milling Machinery. Iron, Steel, Copper, Brass, Zinc and other metals punched for all uses.

Inventor and Manufacturer of the celebrated Slot Cut or burred and Slot Punched Screens.

Mining Screens a specialty, from No. 1 to 15 (fine).

Orders promptly attended to.

San Francisco Pioneer Screen Works,
221 & 223 First St., San Francisco, Cal.
JOHN W. QUICK, Proprietor.

The Best Mining District On the Pacific Coast!

GRASS VALLEY, CAL.

THE BEST NEWSPAPER published in the district is
THE TIDINGS.

Daily and Weekly edition. Gives all the Mining News, Dealers in Mining Machinery and Mining Supplies will find THE TIDINGS the best medium for directly reaching the owners or managers of mines. Investors in mines will find it to their advantage to subscribe.

Many mines are in successful operation, and new enterprises are being instituted and many others are in contemplation.

DAILY, \$6 00 a year; WEEKLY, \$2.50, in advance.
H. S. SPAULDING, Publisher.
T. C. HOCKING, Editor.

FRANCIS SMITH & CO., Manufacturers of Sheet Iron and Steel PIPE!

ALL SIZES.

130 Beale Street, San Francisco, Cal.

Iron cut, punched and formed, for making pipe or ground. All kinds of Tools supplied for making Pipe. Estimates given. Are prepared for coating all sizes of Pipe with a composition of Coal Tar and Asphaltum.

QUARTZ SCREENS

A specialty. Round, slot or hurred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

Zinc, Copper or Brass Screens for all purposes. California Perforated Screen Co., 145 & 147 Beale St., S. F.

THE AIR BRUSH

Applies liquid pigment by a jet of air. Highest awards—Franklin and American Institute as a legitimate art tool. Successfully used by large numbers of the best crayon, ink and water-color portrait artists, and by technical draughtsmen. Saves 75 per cent of time in shading.

Descriptive pamphlet sent free. It points out one way to earn a living. Address AIR BRUSH MFG CO., 9 Nassau Street, Rockford, Illinois.

PACIFIC ROLLING MILL CO.,MANUFACTURERS OF..... Cast Steel Castings and Steel Forgings

UP TO 20,000 LBS. WEIGHT.

True to pattern and superior in strength, toughness and durability to Cast or Wrought Iron in any position or for any service.

GEARINGS, SHOES, DIES, CAMS, TAPPETS, PISTON-HEADS, RAILROAD and MACHINERY CASTINGS of Every Description.

—ALSO—

HOMOGENEOUS STEEL, SOFT and DUCTILE, SUPERIOR TO IRON FOR LOCOMOTIVE and MARINE FORGINGS.

ALSO Steel Rods, from 1/4 to 8 inch diameter and Flats from 1 to 8 inch. Angles, Tees, Channels and other shape Steel Wagon, Buggy, and Truck Tires. Flow Steel. Machinery and Special Shape Steel to size and lengths STEEL RAILS from 12 to 45 pounds per yard. ALSO, Railroad and Merchant Iron, Rolled Beams, Angle, Channel, and T Iron, Bridge and Machine Bolts, Lag Screws, Nuts, Washers, Ship and Boat Spikes; Steamboat Shafts, Cranks, Pistons, Connecting Rods, etc. Car and Locomotive Axles and Frames, and Iron Forgings of all kinds, Iron and Steel Bridge and Roof Work a Specialty.

HIGHEST PRICE PAID FOR SCRAP IRON AND STEEL.

Orders will have prompt attention. Send for Catalogues. Address

PACIFIC ROLLING MILL CO., 202 Market St., San Francisco.

FULTON IRON WORKS, HINOKLEY, SPIERS & HAYES, Proprietors.

[ESTABLISHED IN 1855.]

Office, 218 Fremont St.,

San Francisco.

—MANUFACTURERS OF—

TUSTIN'S PULVERIZER.

MARINE ENGINES AND BOILERS.—Propeller Engines, either High Pressure or Compound, Stern or Side-wheel Engines.

MINING MACHINERY.—Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

MILL MACHINERY.—Batteries for Dry or Wet Crushing, Amalgamating Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores, Water Jackets, etc.

MISCELLANEOUS MACHINERY.—Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Powder Mill Machinery, Water Wheels.

Tustin's Pulverizer WORKS ORE WET OR DRY.

ENGINES AND BOILERS OF ALL KINDS,

Either for use on Steamboats or for use on Land.

Water Pipe, Pump or Air Columns, Fish Tanks for Salmon Canneries

OF EVERY DESCRIPTION.

Boiler Repairs Promptly attended to and at very moderate rates.

AGENTS FOR THE PACIFIC COAST FOR THE

Deane Steam Pump.

SPECIALTIES:

Corliss Engines and Tustin Ore Pulverizers.

Agents and Manufacturers of the Llewellyn Feed Water Purifier and Heater.

FRISBEE-LUCOP MILL CO., —MANUFACTURERS OF—

Centrifugal Roller Steel Mills, FOR PULVERIZING ORES, WET OR DRY,

For Amalgamation or Concentration, and for Manufacture of Cement, Fertilizers, Paint and all other purposes for which grinding or pulverizing is required.

Send for Catalogue and Price List to

FRISBEE-LUCOP MILL CO.,

MINING ENGINEERS.

EVERETTE'S MINING OFFICE.

Pioneer Mining Office of the Northwest Coast.

Having the largest permanent brick assay furnace, chemical laboratory and mining office on the Northwest Coast; with a collection of about 4000 samples of the ores of Alaska, British Columbia, Oregon and the Northwest Territories, and having made personal examinations of nearly every mining camp on the Pacific Slope, from California to Alaska, I am prepared to do any class of legitimate and honest mining work, such as EXAMINING, ENGINEERING, SAMPLING AND REPORTING ON THE VALUE OF ALL MINERAL, COAL AND FIRE-CLAY PROPERTIES, BUILDING STONES, EARTHES, ASSAYS AND ANALYSIS OF ORES, WATERS, CHEMICAL SAMPLES OF ORE, PULPS, "ORGANIC ANALYSIS" WORK, and in fact any work connected with the office of a first-class mining geologist and chemist. Any information mining men may desire to know relative to the MINERAL OR COAL RESOURCES of the entire Pacific Northwest will be honestly given. Address Dr. William E. Everette Consulting Mining Geologist and Chemist, 1313 E Street, Tacoma, Wash.

A. S. GRANT. S. B. CONNOR

CONNOR & GRANT, Millwrights and Engineers

303 CALIFORNIA STREET,
Rooms 20 and 31, SAN FRANCISCO, CAL.

Designers and Constructors of Gold and Silver Mills Hoisting and Pumping Works, Tramways, and everything pertaining to the Mining and Reduction of Ores.

ROSS E. BROWNE,
Mining and Hydraulic Engineer,
No. 307 Sansome St., SAN FRANCISCO.

W. A. GOODYEAR,
Civil and Mining Engineer,
MINING EXPERT and GEOLOGIST.

Address "Business Box A," office of this paper, San Francisco.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metal-Inarglets' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy. Price, \$3.00 post-paid. Sold by DEWEY & Co., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and a absolutely Water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated. Price, \$2 each, or the entire instrument finished in gold plate, \$5.

SOLE WESTERN AGENTS FOR TYLER WIRE WORKS DOUBLE CRIMPED MINING CLOTHS.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.
Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.
Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

Mining Engineers and Metallurgists

Testing and Working Silver Ores

A VALUABLE BOOK

An Illustrated work of 114 pages, for miners and pro-
spectors, by Chas. H. Aaron. Mr. Aaron has managed
to give many useful hints and suggestions, free from
all technicalities, and in such a style as to be easily
comprehended. It is written for the miner, with no
chemical symbols or metallurgical technicalities to con-
fuse those who are not chemists or metallurgists. The
following summary of the contents of the work will give
an idea of its scope.

Under the heading of the first chapter, "Testing Ores
for Silver," we find paragraphs on ore formation, test for
silver, with heat and water, acid or blow pipe. In speak-
ing of testing for a process, the extent and richness of
ore is considered, smelting ores, selecting and working
samples, appliances for testing, roasting, etc. Under
the head of "Working Ores" the author describes Aaron's
process, has something to say of superheated steam, pre-
paration of chloride of copper and coprolite of cop-
per, use of copper and iron, quantity of chemicals, car-
bonate of lime, chloride ores, amalgam, Patchen's pro-
cess, etc. He also describes the methods of working
roasted ores, treatment of base metals, stirring, heat of
furnace, want of sulphur, etc. Under the head of
"Leaching Processes" are the titles Smelting, Mexican
process, Chilean process, Crocker's process, etc. Under
"Pulverizing Machines" are described the various mill
construction and operation, stamp batteries, screens,
Crocker's trip-hammer battery, Paul's pulverizing barrel,
Kendall's battery, Noice's pulverizer, a cheap rock
breaker, etc.

In speaking of amalgamators the author describes a
cheap amalgamator, grinding the ore, directions for mak-
ing a barrel, preventing mechanical wear, use of quick-
silver, copper in bars, Freiberg amalgam, cheap barrel
trough, barrel on rollers, Aaron's amalgamator, separ-
ator, etc.

He describes an improvised retort, roasting furnace,
furnace tools and furnace building. Among the miscel-
laneous mention may be found Aaron's leaching apparatus,
with two or three different arrangements, a wind mill,
sampling tailings, and settling tanks, chloride of cop-
per, etc. Mr. Aaron is a practical miner, of long working
experience on this coast.

Price, post free, \$2.00. Sold by Dewey & Co., Publish-
ers, 220 Market St.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, May 28, 1891.

Cool, foggy weather gave way to a rainstorm, which, though general, was of short duration—doing no harm. The grain crop will unquestionably be the largest on record, with the berry averaging plumper. With large crops and better prices than for years, the outlook is all that can be desired in all branches of trade. The outflow of gold at the East since January 1st aggregates fully \$500,000,000, and that no serious financial results have followed, hardly a ripple, speak volumes in favor of the high standing, financially, that this country has secured. There is not a country in the world that could have done it. Much of the gold sent out was in payment for American securities bought by Eastern operators for a large speculative boom this fall and winter, based on the prosperous condition of the country. Strikes at the East are fewer. All things appear to be settling down to a more legitimate and of necessity prosperous basis.

MEXICAN DOLLARS—The market is quiet at 77 7/8 cts.

QUICKSILVER—Receipts the past week aggregate 133 flasks and exports 360 flasks to Mexico. The market is essentially unchanged.

SILVER—The market has held at fairly steady prices. After next month the Mint will not coin bullion only as requested, but the 4,500,000 ounces of monthly purchases will be continued. The writer still adheres to the opinion that the market will do much better before the end of the year. At the present low prices operators are buying securities, governed by the price of silver, for higher prices when the latter advance. There is no evidence that any European nation is letting go of its silver, but there are unmistakable signs that opinion is steadily setting in its favor. At the East silver is coming more generally into use. Official statistics show that payments in silver certificates and Treasury notes in the first ten days of May amounted to 64.5 per cent of all payments of customs duties at New York, payments in United States notes to 10.8 per cent, and payments in gold coin and certificates to only 24.7 per cent. A year ago the proportion in May was 93.8 per cent gold, 2.6 per cent silver and 3.6 per cent legal tenders. Taken by itself, this change certainly merits attention. When the time of year arrives for large shipments of funds from New York to the agricultural States, with which to move crops, silver will undoubtedly be a rare article. The wheat crop this year is placed at 500,000,000 bushels (about 1,000,000 bushels more than it was in last year) and cotton at 8,500,000 bales, while corn and other cereals promise larger returns than in 1890. To move these, large sums of money will be required, and silver and silver certificates will come in good play.

LIME—Receipts the past week aggregate 4378 bbls, and exports by sea 430 bbls. to Honolulu. The market is essentially unchanged, although it is stated that slight concessions are obtainable from one or two agencies.

LEAD—The market is fairly steady. The demand is good for the season. It is said that at present prices, and the low freights from England, shipments can be made from that country.

TIN—Our market is reported unchanged. Eastern advices report heavy stocks of plate, more than enough for at least a year to come. Pig tin in Europe is stronger owing to a lessened output and a fair demand. Plate in England is easy.

IRON—It is claimed that notwithstanding the large stocks here, the shipments on the way are quite heavy. These shipments are largely induced by the low freights to this port. The consumption on this coast is said to show a much larger volume than at the same time in 1890. At the East the consumption is enlarging. According to cablegram to Iron Age, there is quite a speculation movement in warrants in England.

COPPER—The market is far from satisfactory. Of necessity when the market drags, consumers take sparingly; this is the present condition at the East and also abroad. New York is reported weak with Lake selling below 13c, Arizona below 12 1/2 c, and casting brands 11 to 11 1/2 c.

COAL—Imports the past week aggregate as follows: Coos Bay, 1350 tons; Departure Bay, 2500; Seattle, 506; Baltimore, 1046; Nanaimo 4000. Total, 9356 tons. The market continues unsatisfactory to the selling interest. The stock on hand is large, while shipments from England are exceedingly large, as they are also from Atlantic ports. Australia will soon begin to increase her shipments as the wheat surplus there is well provided for. Our exceptionally large crop of wheat is causing vessels to seek this port, and coal is largely used for cargo.

Wednesday.....	44 5-16	97	13 00	4 35	20 25

Borax is steadier. Tin is a shade easier. Lead is strongly held. Copper is irregularly weak. Iron has a stronger tone, but is not quotable higher.

Mining Share Market.

Mining shares the past week moved in a peculiar manner. While North End stocks held weak and apparently sold down, Middle and Gold Hill stocks gradually gained strength. This seeming anomaly indicates that, in the recent active movements, the pool sold considerable North End stocks, but had to take in large lots of the others. The writer still has faith in the market, and has reason to believe that a person who buys stock and pays cash and will not be afraid of either a small decline or an assessment, provided either or both come, will come out considerably ahead. This, of course, has reference more particularly to stocks that did not move up during the recent deal. There are many well-informed and successful operators who look for a big deal this fall, based on larger ore development than has been made for several years. While this may be the case, yet experience has taught dealers not to wait for too big a boom (always put out for a purpose), but sell when a 50 or 100 per cent profit is in sight. They have learned also by experience to buy for cash only and not sell if prices go down, for they know that it is only a question of time when they come up again.

All information at hand warrants the belief that at the East a movement has been underway for several weeks, if not months, partly looking to a big bull campaign this fall in railroad securities, and that a powerful moneyed syndicate has been and is still buying all the American securities Europe has for sale, well knowing that America's large crops and the railroads higher freight and passenger rates will admit of dividends the paying of which will allow the syndicate to unload at a large profit. In this move it is thought the mining stock pool or trust company will take a hand and bull up their securities. As a preliminary to this, Jim Keene is being pushed to the front at the East, with this coast Maurice Schmidt who is held in reserve, with Crocker and two or three other first class brokers will come more prominently forward. But of this move more will be known later on, for it is said that there is a strong clique or pool combined to fight the old manipulators, mine managers and mill ring.

Con. Virginia will carry over from this month a surplus, after all expenses are paid, of at least \$200,000. Chollar is more than paying expenses. Overman is accumulating a surplus. Con. Imperial bullion product aggregates about \$10,000 in coin, which about pays expenses. Yellow Jacket will soon be a larger producer. Crown Point, Challenge, Seg. Belcher and two or three more stocks are to be assessed in next month.

News from the Comstock mines is not only confirmatory of the good advices heretofore published, but it also points with unerring certainty to the opening up of a large ore body before the end of this year, but where, no one has as yet been able to satisfactorily answer. The writer believes it will be in the mine in which the pool owns all or about all the stock. In Union, progress is making to pump out the mines. On the 2400-foot level, there is a large body of rich ore. Active work in Ophir, Mexican, Union and Sierra Nevada develop the 1465-foot level to the west, where rich ore has been found in two of them. In Con. Virginia, attention is still attracted to the 1100-foot level. Of course this is to throw outside dealers off the track. The company is accumulating a large surplus fund so as to resume dividends in July next, if not, but hardly likely, sooner. In Best and Belcher, they are doing more interesting work. In Hale and Norcross and Savage, the powers that be, continue to blind operators regarding important work that has been and that is being done. In Chollar, they ran into a 50-foot ledge lying west of the Comstock west wall. Our advices indicate the ore much richer than the managers wish to have known. In Potosi and Bullion, it looks as if the managers are about ready to show up some ore so as to make another deal. They can do this at any time desired, so as to collect assessments, probably for future inside assessment dividends. Work is progressing favorably in the Ward shaft to develop the mines contingent to it. Quiet reports are being put out about a strike of rich ore in Challenge. In Yellow Jacket, arrangements have been made to crush more ore. The ore that is being taken out is gold-bearing, and assays from \$40 to \$80 a ton; but it is hardly likely it will go over \$20, if that in battery assays, the balance going elsewhere—certainly not to outside stockholders. The work in Crown Point, Belcher, Seg. Belcher and Overman deserves close watching.

It is said that Col. Mackay has succeeded in getting control of the Yellow Jacket, Crown Point and Belcher. From outside mines, all news set strongly in favor of the belief that a good up move is near at hand.

Scientific and Educational Lectures.

The following is a partial list of subjects which Rev. John Dickinson, of University P. O., Los Angeles Co., is prepared to treat:

1. A Hurried Glance at Mother Earth.
2. A Closer Look at the Earth's Crust.
3. Minerals—Their Chemistry and Geometry.
4. The Moon.
5. The Geology of the Stars.
6. Evolution—What, Whence, Whither?
7. Some Readings from Nature's Great Stone Book.
8. A Winter in the West Indies.
9. Science Teaching in Schools.
10. Literature Teaching in Schools.
11. Biology. (One, two, three or four lectures.)
12. Physical Conditions of Success in Teaching.
13. Psychology as Related to Physiology.
14. Botany in the High School.
15. Zoology in the High School.

The first eight numbers are better adapted for evening public lectures, and are of general interest. The remainder are more suitable for special institute work.

Knowing Mr. Dickinson (who is a brother of the celebrated lecturer, Anna E. Dickinson,) long and well, we would recommend county or city school superintendents, lecture committees, Chautauque Circles, or other persons who may desire single lectures or courses of lectures on scientific subjects, to correspond with him for further information.

Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this Coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific Coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this Coast. They are the only post office on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That this is understood and appreciated, is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (8 F.) from week to week and year to year.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

E. A. BELCHER, Esq., whose professional card appears in another column of this paper, is a brother of Judge Belcher of the Supreme Court Commission, with whom he was sometime associated at Marysville. Mr. Belcher is an experienced and careful lawyer and gives special attention to mining law and the securing of patents for mining claims.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for \$2 per volume of six months. (Per year (two volumes) \$5.) Inserted in Dewey's patent holder, 50 cents additional per volume.

Sales at San Francisco Stock Exchange.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further Information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), London, October 8, 1888.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs;" for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if need be. Circulars and testimonial letters furnished on application.

JOSHUA HENDY MACHINE WORKS,

39 to 51 Fremont Street, San Francisco, Cal.

(PATENTED.)

Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

Original Empire Mill and Mining Company,
Principal Office, 401 California St., cor. Sansome, S. F.
Location of Works, Orass Valley, Nevada Co., Cal.

ORASS VALLEY, NEVADA CO., CAL., Nov. 10, 1885.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:

GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID McKAY, JR.,
[Signed] Sup't North Star and Original Empire Mining Co.

N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 80 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.

121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS, Varying from the fraction of 1 up to 15 and 20-horse power, unequalled for all light-running machinery.

Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

EDISON ELECTRIC DRILL MOUNTED ON TRIPOD.

ELECTRIC DRILL MOUNTED ON COLUMN.

Blasdel's Concentrating Belt.

An engraving on this page shows the patent concentrating belt made by the Blasdel Concentrating Belt Co., 419 California St., this city. The peculiarity of this device is that the flanges or edges of the belt stand at an acute angle, inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers, avoiding breakage of the flanges. This belt, at intervals of four feet, has a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and quicksilver, which might escape from a belt

with an entirely smooth surface. The cut shows the construction of the belt very clearly.

Electric Percussion Drills.

The introduction of electricity in mining and other underground work has not, until recently, kept pace with its other applications, notwithstanding its peculiar adaptation to just such situations. The reason for this has been that so long as power drills could only be successfully operated by compressed air, it was difficult to convince the mine operator of any material advantage to be gained by the introduction of the electric current so long as he had to maintain at the same time his compressed air plant. A practical and simple electrical percussion drill was, therefore, the key

to the situation. The Edison General Electric Co. of New York, appreciating this fact, obtained full control of an electric drill, which in every way meets requirements, viz., a drill making use of the principles of the "Marron system of percussion tools."

The dynamo is of the ordinary Edison type, and may also be used for operating motors, etc. The moving parts of the drill are confined to an iron plunger without commutator or collector, and there are no electrical connections that can be disturbed by jarring, or affected by moisture or dropping water. The only wearing parts are the guides on which the drill rod works.

Neither an insufficient nor an excessive feed can result in damage to the drill, the peculiar automatic electro-magnet action immediately reducing the stroke to a quiver in case the drill fails to reach the rock, and accommodating its length to suit the situation when the normal stroke is not permitted.

The frequency of the stroke permits of more rapid work with less wear and strain on the bit than in power drills of ordinary type. The drill can be operated or taken apart and replaced by ordinary workmen with no knowledge of electricity.

The drill, cuts of which are here shown, consists simply of a reciprocating iron bar impelled up and down by the alternating action of two coils of wire. An iron envelope, consisting of a piece of boiler tube seven inches in

diameter and about two feet long, contains two solid coils of copper wire through which reciprocates an iron bar about two inches in diameter. At the forward end of the machine this bar travels through a long bearing. The outer end of the bar carries a chuck, into which the bit or drill is fastened. The whole is mounted upon a slide with a feed screw for advancing the machine to the rock. The machine is mounted upon a column, tripod or quarry bar, in the usual manner. The ends of the wire coils within the casing are brought to the connecting plugs on the outside of the casing. A flexible cable of any desired length, composed of three insulated stranded wires, leads from the source of electric supply to the drill, and a special connection piece on the end of the cable connects the wires of the cable with the connecting plugs on the drill.

To set the drill in operation it is only necessary to thrust the cable connector into its socket on the drill, the machine then starts. No switch is used. There is no commutating or current shifting in the machine, and nothing corresponding to a valve on an air drill. The shifting of the current from one coil to the other to make the stroke is effected by a peculiar arrangement of dynamo connections and chronites. The drills are operated in parallel; three wires lead from the two drill coils to the generator, comprising two distinct circuits, each circuit including similar coils in the drills. Over these two circuits electrical impulses are sent in alternation. One impulse moves the iron bar or plunger back, and the next moves it forward; thus the drills all move together and in synchronism with the generator. The drill makes about 600 strokes per minute, and the stroke of the plunger is from three to four inches.

The drill will cut at the rate of two inches per minute in the hardest granite with a one and one-half inch bit, and absorbs about five horse power. It is adapted

(Continued on page 60.)

ELECTRIC HOIST FOR MINES.

THE BLASDEL CONCENTRATOR BELT.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EBS.

Loss of Gold in Milling.

EDITORS PRESS:—The article of Mr. Phillip Mixsell, of Idaho Springs, Colorado, would have been sooner answered but for my absence. In reply, I will say that if Mr. M. gets 85 and 90 per cent with his mill, working with water, as he states, he does wonders; and here I must express my doubt—not that I question his word, but from the fact that he does not properly sample the ore so as to get the real value. I agree with Mr. M. when he says: "When you get 85 per cent on assay the proof has got to be awful strong to swallow it," and I will add especially when 25 per cent is sulphurets, and especially, again, when the base is zinc, lead and copper. Now, as to his testing, he "takes frequent samples every hour." There is only one absolutely true way to test gold rock, and that is to crush the entire lot you are to work dry, and then sample the entire lot and compare assays with milling results; or, if working wet, run all into tanks and settle until the water passes off clear, and then it will have some gold in.

There is no use of persons flattering themselves that they get 85 per cent of any gold rock by a wet-working battery and use what they may. I am done with stamps, except to crush rock; outside of this they are the curse of the miner—in fact I am about done with wet-working reduction anyhow, and take the stand that all gold ores must be reduced dry. It is about time stamps were thrown one side; they produce more failures than successes, and it is time this dashing, splashing, flooding system of handling gold rock was stopped.

It is all working in the wrong direction, and the vast number of failures and idle stamps is the best evidence of this. There is only one true way to handle gold rock, crush it dry, and manipulate it in slow motioned machines, let them be what they may, and work to get the gold and not to do your heat to splash it about by high agitation so as to run the most passable away. Stamps sometimes pay because their is a large value in the rock, but then they waste as much as is gained unless where gold is very coarse.

You can combat these ideas all you please, you will finally come to dry working. This question of the loss of gold is important to the miner and country, and the more discussed the better.

Mr. Mixsell throws out a very valuable suggestion when he says it would be a great hit if your State geologist would take this matter up and devote part of his most excellent annual report to the different milling plants, and gives us figures upon these different kinds of mills. A full discussion by mill men on this most important of subjects, cannot but prove a great boon to this great and growing industry and I will add, make a critical investigation as to the per cent of metal saved. It would be slow work, but a very valuable one as it would impart information productive of profit.

ALMARIN B. PAUL.

Middle Creek P. O., Shasta Co., Cal.

Letter from San Bernardino Co., Cal.

EDITORS PRESS:—The town of Daggett, whence I write, is situated on the south bank of the Mojave river, at a point 85 miles north from the city of San Bernardino, the county seat, with which it is connected by the California Southern railroad, the Atlantic & Pacific railroad passing through it. Daggett, which contains about 400 inhabitants, including mill hands, is the receiving and supply point for the Calico mining district, lying six miles to the north, as well as for a considerable extent of country adjacent. The Calico constitutes the most important mining district in San Bernardino county, it being from these mines that more than three-fourths of all the silver produced in California is obtained. Although not noted for its churches or literary institutions, Daggett is a prosperous town, having about recovered from the effects of the destructive fire that visited it nearly one year ago. It is a remarkably healthy place, the climate, except during the summer months, which are excessively hot, being mild and agreeable. The water is good and abundant, being supplied by the Mojave river, here quite a large and never-failing stream.

Situated in or near the town are four ore-reducing mills, two of these, the one carrying 60 and the other 15 stamps, being owned by the Oro Grande Company and run on ore from their Waterloo mine; of the other two, one is a 10 stamp and the other a 5-stamp autum mill, neither being operated with much regularity.

A local event much talked of here is the sale of what is known as the Doe property to an English syndicate for a large sum of money. From all that can be learned, this sale is dependent on the favorable report of James D. Hague, an old California mining expert, now a resident of New York, and daily expected here. This property includes the Garfield, Occidental, Mammoth, Ontario, Odessa and several claims of lesser note. On the ore from these mines, a 20-stamp mill, located at the town of Calico, has been running for a number

of years past, making a large and profitable production of bullion. It is whispered about that negotiations looking to a sale of the Oro Grande Company's property are also on foot.

Judge James Walsh, pioneer mover on the Comstock lode, is domiciled here, looking after some mines situated off to the east, that he has bonded, and, according to all accounts, on most favorable terms. The judge has about effected an arrangement with San Francisco capitalists for shipping the ore from these mines on a large scale. The enterprise promises to turn out well, the ore being of high grade, easily mined and very abundant. To what point it will be taken for sale or reduction has not yet been determined, though most likely to the Sishy Works, near San Francisco. This plan of shipping ore is growing in favor, not only here, but also in Arizona and even farther south, there being a splendid field for this new industry in Northern Sonora, where the conditions are said to be exceedingly favorable to its practice.

In looking over the last report of the California State Mineralogist, it will be observed that very little is said therein about these Calico mines, which, as being the only large silver producers in the State, it would naturally be expected would have received more attention. This omission was due to the following circumstance:

At the very beginning of last year, Mr. Ireland, State Mineralogist, appointed James H. Crossman Assistant in the field to examine and report on the mines and the mineral resources of San Bernardino county, a work that he at once entered upon. After having been so engaged for two or three months, Crossman entered the service of the Temescal Tin Mining Company, and the position he had held becoming vacant, Dr. Henry Degroot was by Mr. Ireland appointed to fill it.

Dr. Degroot, on reaching Calico, was given to understand that Crossman had worked up that district he having spent some time in the vicinity. As he had a vast extent of country to traverse the doctor pushed on, in the confident belief that his predecessor in the field would furnish the Mining Bureau with all needed information about this important locality. For reasons unexplained, however, no such information ever reached that institution; hence this awkward and unfortunate omission. It is hoped that in the next report of the State Mineralogist this oversight will be duly atoned for.

J. R. M.

Daggett, May 21st, 1891.

THE LOCOMOTIVE OF THE FUTURE.—The enormous mass of extra dead weight due to the carrying of the boiler, fuel and water in the old locomotive will be entirely unnecessary in the railways of the future, which will be propelled by electricity. Unquestionably the future electro-locomotion will show a motor on every axle, or at any rate upon two axles of each car, and every car running as a unit, in which case they can run coupled together in a train or not, as may be convenient—a strong protest against carrying this enormous dead weight of a locomotive for absolutely no purpose. We have the weight of the cars plus the passengers or freight, for purposes of traction, even if we make our cars in future of lighter material. In speaking of the lightness of the future conveyance by rail, a well-known authority says we shall not only use steel and aluminum, but paper, India rubber and other fibrous substances, which will give us remarkably light cars, far beyond anything we now speak of practically. Just as a wheelbarrow is to a bicycle, so will be our clumsy cars to the future ones. To have a big motor car loaded with tons of ballast to give it traction is following the path of steam locomotion; in all probability, the necessary adhesion will soon be gained by electricity.—*Electric Power.*

In a lecture delivered before the students of Sibley College, Mr. O. Chanute, president of the American Society of Civil Engineers, dealt with the question of aerial navigation. Reasoning from the results obtained by Captain Renard, with "La France," he concludes that with a balloon 330 feet long, with a maximum diameter of 55 feet, a speed of from 25 to 30 miles an hour might be attained. Mr. Chanute thinks, however, that the problem of flight is more likely to be solved by means of the aeroplane than with the balloon. To obtain a speed of 25 miles an hour with aeroplanes he estimates that 5.87 horse-power would be required per ton of weight. The inclination of the supporting surface should be between 1° and 2° to the horizon. The great difficulty, Mr. Chanute states, is that of obtaining a light enough motor. The weight should not exceed 50 pounds horse power, and the lightest steam engine he is acquainted with, specially built for aerial navigation, weighed 13 pounds per horse power. We may point out that Mr. Brotherhood has obtained a horse power with but little over one pound of weight in his three-cylindered engine used in Whitehead torpedoes. These engines work with compressed air.

SO FAR as known, the first death from artificially conducted electricity was that of Professor Kohnan of St. Petersburg. He devised what was practically the first lightning-rod, and was killed by it. He ran an iron to the top of his house, in present lightning-rod manner, and waited for a thunder-storm. It came. There was a terrific flash of lightning. The professor's appliance worked well, and he was found dead by the side of it.

The New Land Laws.

General Land Agent Sheehan has received an important communication from the Department of the Interior in the shape of an interpretation of the recently enacted Timber Culture Act.

Attention is first called to the section of the new law prohibiting the further entry of public lands for timber culture unless the right to make such entry had accrued or was accruing at the date of this Act, March 3, 1891.

In dealing with existing entries the right is extended to persons having the following qualifications to commute their entries in certain cases at the rate of \$1.25 an acre: The person shall have in good faith complied with the provisions of the Timber Culture laws for four years; he shall be an actual bona fide resident of the State or Territory in which said land is located.

Final proof for the commutation of timber culture entries shall be made as other final timber-culture proof is made, and shall satisfactorily exhibit the facts necessary to make purchase. Returns will be made as in commuted homestead entries under existing practice, but with proper annotations to indicate the transaction as a commutation of timber culture entry under this Act.

The new Act amends the Desert Land law of March 3, 1877, in the following particulars: At the time of filing declaration a map of the land exhibiting a plan showing the mode of contemplated irrigation, which shall be sufficient to thoroughly irrigate and reclaim the land and prepare it to raise ordinary agricultural crops, and the source of the water to be used must also be filed.

Entrymen shall expend, for purposes stated, at least \$3 an acre—\$1 an acre each year for three years—and shall file proof thereof each year, the proof to consist of the affidavits of two or more witnesses, showing that the full sum has been expended and the manner in which expended, and at the expiration of the third year a map or plan showing the character and extent of improvements. Failure to file proof during any year shall cause the land to revert to the United States, the money to be forfeited and the entry canceled.

The limit for making proof is four years from date of filing declaration. The proof must show the citizenship of the party offering it, and the cultivation of one-eighth of the land in addition to the reclamation. Final entry may be made and patent received at any time prior to expiration of four years, when all required proofs, as stated, have been made.

Entries made under the old law may be perfected under either the old or new law, at the option of the claimant.

Assignments are recognized, but the amount of land that may be thus held, prior to issue of patent, is restricted to 320 acres. Assignees must prove their assignments by filing in the local Land Office an affidavit and certified copy of the instrument under which they claim, and make affidavit of the amount of land held. The provisions of the original Act and the amendments are extended to Colorado.

The right to make desert-land entry is restricted to resident citizens of the State or Territory in which the land is located.

The new Act extends its provisions to settlers under other settlement laws, in addition to the pre-emption and homestead laws, and admits of transfers for right of way for canals or ditches for irrigation or drainage, church, cemetery or school purposes, or for the right of way of railroad.

The new Act repeals all laws allowing pre-emption of public lands by individuals, but provides for perfecting claims previously initiated, according to the laws under which they were initiated.

A person already the proprietor of more than 160 acres of land in any State or Territory cannot acquire a right under the homestead law.

Those proposing to commute their homestead entries to cash must make proof of settlement and of residence and cultivation of the land for 14 months from the date of entry.

The Ventilation of Tunnels.

Mr. Josef Purzl, assistant city engineer of Vienna, points out that the aim in every rationally designed ventilating arrangement for tunnels is to utilize natural forces for the movement of the air, and that only when these prove insufficient or cannot be made available mechanical means are resorted to. Accordingly, a knowledge of the laws of these forces alone can aid in determining the expediency of heavy or light tunnel grades, and the question of the admissible length of tunnel in which there is to be no artificial ventilation. Barometric and thermometric differences are the prime factors in the problem. To these must be added atmospheric motions or winds. Mr. Purzl, with this basis, enters into a long mathematical discussion of the laws of natural ventilation, and applies them to the St. Gotthard, the Mont Cenis and the Arlberg tunnels. Of these, only the Mont Cenis tunnel is provided with mechanical ventilation. It was expected that with the difference in level between the ends of the tunnel of 133 meters (about 436 feet), there would, under all possible conditions, be a continuous current of air through the tunnel, from north to south. This expectation, however, was not fulfilled, and provisions were therefore made for arti-

cial ventilation. While the condition of the atmosphere in the tunnel was not dangerous to passengers, it proved troublesome to the workmen. An eight-inch pipe was laid between the tracks from one end of the tunnel to the other. It was supplied with air under pressure from the Italian end, and was fitted at intervals with cocks from which the air could escape. This arrangement is presumably still in use. In the matter of grades in tunnels, Mr. Purzl directs attention to the circumstance that with a heavy grade, much smoke will be emitted during up trips, and practically none during down trips, and that the latter, therefore, are always the more agreeable ones, although the motion of a train on a down trip frequently interferes with the natural current of air, which is in an upward direction. His conclusion, in the main, is that for large tunnels, the lightest practicable grades are advisable, and that tunnels even longer than any now existing could be operated by having light grades and natural ventilation.

The Tower at the World's Fair.

Passing the Woman's building, the visitor can turn toward the northeast and inspect the foreign and State buildings in the northern portion of the park, of which he is supposed to have caught a general view from the steamboat deck, or he can turn sharply to the west into Midway Plaisance and ascend the Proctor tower. This will be constructed of steel and be 1050 feet high, or about 100 feet higher than the Eiffel. From its top the view obtainable of the Exposition grounds and buildings and of the great city lying to the northward will be magnificent beyond all description.

West of the tower, along the Plaisance and overflowing into Washington Park, will be a large and curious aggregation of structures, including probably some of the foreign and State buildings, and many of semi-private construction and of a nature that cannot yet be described. Almost innumerable structures and exhibits, such as reproductions of famous buildings, etc., most of them novel and striking in character, have been proposed, and it is not yet possible to tell how many or which of them will be erected. That there will be an astonishing array of them there can be no doubt, and unquestionably some of them will be important and exceedingly interesting features of the great fair.

All of the important buildings will stand on terraces four feet above the general park level, thus greatly improving the general landscape effect and rendering their own appearance more imposing. From scores of domes and towers and minarets, flags and streamers will be floating, and both the exterior and interior of the building will be "warm" with a liberal display of color. The beautiful park, with its magnificent array of architecture, will surely present one of the finest spectacles the eye of man ever beheld.

Early Railroad.

When railroads were first introduced, then engineers, as we call them—or the engine drivers, as they are called in England—ran their trains almost as they liked, making up time when they had fallen behind, plying up such information as they could as to the state of the track ahead of them, and, for the most part, plunging ahead with their machines without much more than a surmise whether they should bring up at their destination, or at the bottom of some high embankment.

Some of the results of this want of system would have been amusing, if they had not been disastrous. Mr. Laurence Oliphant, an English traveler and author, tells in one of his books a rather grim story of a trip which he made by rail, in 1855, from Chicago to New York. Over a part of the distance the train made the extraordinary speed, for that time, of 50 miles an hour, and presently it ran off the track.

Fortunately, the cars were latched in a soft clay ditch, and no one was seriously hurt; and in the midst of the commotion, Mr. Oliphant says he heard the engineer thus admonish the switchman, whose carelessness had caused the accident:

"Now, Tom, this is the third time you've forgot to set that switch, and the last time there were 20 people went under and the rest were bruised. So mind what you're about, and don't forget that switch again, for if you do I'll tell the boss!"

A RAILROAD ON TREE TOPS.—It may not be known outside of the neighborhood in which it is situated, but it is nevertheless a fact that in Sonoma county, Cal., there exists an original and successful piece of railroad engineering and building that is not to be found in the books. In the upper part of the county named, near the coast, may be seen an actual railroad bed on tree tops. Between the Clipper Mill and Stuart Point, where the road crosses a deep ravine, the trees are sawed off on a level with the surrounding hills, and the timbers and ties laid on the stumps. In the center of the ravine mentioned, two huge redwood trees, side by side, form a substantial support. These giants have been lopped off 75 feet above the bed of the creek. This natural tree bridge is considered one of the wonders of the Golden State, and for safety and security far exceeds a bridge framed in the most scientific manner.

Human Capacity.

Is the human race endowed with talents, tastes and capacities so as to furnish to-day the requisite number to conduct the varied affairs of life and business, so that every department could be properly filled, and all be occupied?

In reply to this question, we may say that human nature is susceptible of varied culture, and that all the faculties exist in all men (except idiots), but the faculties are naturally developed by the incidents and circumstances which may act upon given tribes or classes of people; and if the question were asked, "Are all men now qualified to adapt themselves to the different economies of life?" we would say "NO." A great majority of mankind to-day is adapted to the commonest drudgeries only, because the majority of the race has not been cultivated so much in the faculties of philosophy, and

colonies on the false basis of hunting for precious metals, and their colonial civilization is faulty. The English have colonized for homes, farms, mechanism and trade, and their footsteps have been firm, and the results permanent and powerful. France cultivates ornaments and aesthetics, and we have a nation of fancy, style and decoration. The Scandinavians, by necessity, followed the sea, and they became navigators and the explorers of the world.

If we could find a country with the soil and climate adapted to the development of every useful trade, art, or occupation, doubtless the public would become classified so as to adapt a proper number of persons to each department of effort and achievement pertaining to all the phases of an excellent civilization. New England could not raise wheat, and Illinois lacks the water-power to be, like New England, a manufacturing region. The faculties become cultivated by practice, and practice is invited by

The Buffalo Pitts Traction Engine.

The season of special activity in traction engines is at hand. It seems likely from the many uses to which engines of this sort can be put in California that they will become an all-year resort for the large-scale California farmer, but at present their chief sphere is found in harvesting our great grain crops. The engraving on this page shows the Buffalo Pitts Traction straw-burning engine, as especially built for the California trade, conducted by Baker & Hamilton of this city and Sacramento. The engraving gives an excellent idea of the design of the machine, three-quarter view, as the photographer would say.

The Buffalo Pitts Traction engine has been in use for some time in California for pulling combined harvesters, plowing, etc., and the manufacturers in their circular make the fol-

It is near the junction of the St. Clair river with Lake Huron, and connects the towns of Port Sarnia, Ont., and Port Huron, Michigan. The railroad which runs through the tunnel is the connection of the Grand Trunk railway of Canada with its line in Michigan. The tunnel is 6000 feet long and the approaches are 1950 and 2500 feet respectively, making a total length of over two miles. The approaches have a grade of 105 feet to the mile, and a heavy locomotive is required to haul trains through the tunnel and up the grade of the approaches.

The locomotives are known as tank locomotives having no tender. There is a tank on each side of the boiler, and their capacity is 2000 gallons. There are five pairs of driving wheels 50 inches in diameter. The wheel base is 18 feet 3 inches. The cylinders are 22 inches in diameter, having a stroke of 28 inches. The boiler is of steel $\frac{3}{4}$ of an inch thick, and is six feet two inches in diameter. There are 180 fires

BUFFALO PITTS TRACTION ENGINE.

ethics, and aesthetics, and mechanics, as it ought to have been; hence some nations are behind in arts, sciences and literature.

On the seacoasts we find men developed in reference to following the water, and seaman-ship is chiefly the result, and men have become almost amphibious. In other sections we find that the mechanical elements have been cultivated until the strength of the character finds its outlet in mechanism. We know of a town in Massachusetts where they nearly all tend toward the ministry and missionary work. Somebody has succeeded in that direction, and others have followed, until the strong current in that town is toward the ministry, as in other towns in the same State the current is toward navigation, especially the fisheries, and in others toward mechanism. In Kentucky there is a public sentiment that runs toward fine horses, and fine horses are the result. In other sections, not denying Kentucky her share, law, politics, statesmanship, public affairs seem to be the aspiration of the people, and in California and Colorado mining is the drift, and millionaires are the prayer, if not the song, of the people. The Spaniards have made most of their

necessity, and necessity is met or not met by opportunity, hence culture in diverse directions depends largely upon the wants of the people and the opportunities for such development. A hundred years from now this country may illustrate a harmonious division of talent and its adaptation to the different pursuits and attainments of life.—*Phrenological Journal*.

MECHANICAL IMPROVEMENTS.—A writer in an exchange says that the past two years have developed more improvements in mechanical devices than any 20 years preceding. During that time almost every branch of business has been more or less revolutionized by new mechanical appliances or new processes. It is a remarkable fact that it is more applicable to the American people than to any other nation that whenever any new device is brought out or any new process introduced, even before its utility is fairly demonstrated, in many cases hundreds and thousands are found ready to adopt it.

It will not do to run a cast iron fly wheel faster than 80 feet per second.

lowing claims for it: 1st, that it will pull any horse combined harvester built; 2d, that it will pull twelve 12 inch plows or more, according to condition of soil; 3d, that straw, wood or coal can be used for fuel, and full steam maintained with either kind of fuel; 4th, by reason of its large horse power and comparatively light weight is a perfect engine for road hauling.

The Largest Locomotive Ever Built.

A huge locomotive, the largest ever built in America and probably the heaviest ever built in the world, is now at the Baldwin Locomotive works in Philadelphia, and will be shipped next week to the St. Clair Tunnel company.

Four locomotives of the same kind have been built at the Baldwin Works for the company. Each is guaranteed to haul a load of 760 gross tons of cars and loading up a grade of 105 feet to the mile—equivalent to a train of 25 or 30 loaded freight cars. The St. Clair Tunnel company, for which the locomotives have been built, controls the line of railroad running through the tunnel under the St. Clair river.

24 inches in diameter and 13 feet 6 inches long. The fire-box is 11 feet long and 34 feet wide. The locomotive is too heavy for some of the bridges it will have to cross on the way, and the oaks, tanks, side rods, and other parts will have to be taken off and shipped separately.

A GREAT ENGINEERING FEAT.—The greatest engineering feat in the history of the anthracite coal mining is about to begin. It is the commencement of what will be known as the Jeddo tunnel, which will be driven for the purpose of draining the flooded mines of Jeddo and Harleigh. It will be constructed from Butler valley, Pa., to the bottom of Eberly's mammoth vein, a distance of three miles through solid rock, to be eight feet square in the clear. The scheme of tunneling through the mountain first occurred to John Markle, who is to be president of the company, which will bear the title of Jeddo Tunnel Co., Limited. It will open an inexhaustible supply of coal and furnish employment for thousands of people for many years to come. It will also serve the double purpose of draining all the coalfields in the valley.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SOUTH EUREKA.—*Ledger*, May 30: Work was commenced on this property last week. A shaft is being sunk at a point selected by the superintendent, J. F. Parks, as the most available site. After reaching a few feet, small bunches of quartz were encountered, although of no special significance, beyond the mere fact that gold quartz exists there, considerably elated some of those interested in the movement. A very general opinion prevails that there is a mine within the dimensions of this claim. The surface is not disturbed, as in many other locations. The claim forms an elevated plateau, with the surface comparatively level. This naturally leads to the impression that underneath, the formation will be found as unbroken as on top; so that if a quartz ledge is discovered, it will in all probability be a strong and continuous one. The machinery from the Ilex mine at Rich Gulch, Calaveras county, will be brought over and erected on the property as soon as the workmen are ready to put it in place. This machinery is first class in every respect, and cost originally over \$15,000, we are informed. The South Eureka purchased it for \$1700, from what we can learn. It is as good as new. Reports reach us that J. Griesbach has struck a rich vein of quartz in his claim in Pioneer district. The ore is estimated to go from \$30 to \$40 a ton. At the Clinton Con, it is the intention to put up hoisting machinery and go to sinking in the near future. So far the rock has been taken from a tunnel and above the tunnel level. While there is a large body of ore to operate upon above the tunnel, still at the depth of 200 feet from the surface it is only a question of time when it will be exhausted. It is therefore wise, while the property is on a good financial basis, to develop other ore bodies below the tunnel. There is talk of putting up hoisting machinery on the McAtto mine also.

Butte.

QUARTZ.—*Oroville Mercury*, May 28: Major Reynolds of the American Eagle Quartz mine, situated near Merrimac, is in town en route to the mine. His company has done a great deal more work there than our people realize. They have gone in about 3000 feet on the ledge at a 300-foot level and will crush an average of 25 tons a day during the coming season. This company has expended in the neighborhood of \$40,000 in the development of the American Eagle, and Major Reynolds is now delighted with his prospects of getting back the principal with a large interest. He thinks that the prospect for Butte county quartz development is brighter than ever before.

MORE RICH ROCK.—Frank and Tom Salsbury and Steve Henderson have struck it rich again in a quartz ledge near Inskip. They found a remarkably rich ledge a few weeks ago and, with a hand mortar, two of them took out \$760 in 16 days, and had to carry the rock several hundred yards to wash it after it was pulverized. This latter find is the third ledge located by these young men in that neighborhood and they stand a good chance of becoming bonanza kings. They don't know the extent of their ledges, but the rock is astonishingly rich in free gold.

Calaveras.

NOTES.—*Calaveras Prospect*, May 30: The Lloyd mine on the Jackson lead has several men employed in sinking a shaft and getting ready for more thorough work. The Augustini and Spinola mine on Central hill will, we hear, start up in a few days. Central hill seems to be the center of attraction these days, and all the mines are showing signs of activity. F. J. Haswell is all ready to commence mining operations at Barker's Flat, on the Stockton road. He has a boring machine in position to be operated by two horses. The Orchard mine is still hoisting gravel.

WEST POINT.—*Calaveras Chronicle*, May 30: The Blazing Star mine has just crushed rock that yielded over \$10 per ton. The Bardsley Brothers have just crushed about 16 tons of ore that paid well. Wickham's mill is now running on custom rock. Three loads of machinery have recently passed through town on their way to the mines.

El Dorado.

BLAIR CLAIM.—*Mt. Democrat*, May 30: Large teams have been engaged during the past two weeks in hauling material from the Baker's Divide ranch in Placer county to the Blair claim at the Nine Mile House. Work on this claim is being pushed rapidly, and when the improvements now in the course of construction are completed, more men will be put on, and the tunnel pushed at the rate of ten feet per day. That amount has already been driven several times.

Nevada.

MINING AT FRENCH CORRAL.—*Grass Valley Union*, May 29: The Milton Mining Company at French Corral, is now working gravel successfully by the elevator process. By using a strong stream of water the gravel is forced up an elevation of 32 feet and washed in sluices, and then the debris is deposited in a restraining reservoir on ground that formerly was washed out. The escaping water is then clearer than that which is carried in the bed of the Yuba. The elevator was experimented with for some time before it worked satisfactorily. The agents of the Anti-Debris Association, who make regular visits to the mine, have found no fault with this elevator process, as the washed gravel does not escape to the river.

Shasta.

MIDDLE CREEK.—*Cor. Shasta Courier*, May 30: Work on the Miller mill and concentrating works is progressing. They are putting the machinery in place, and the mill will soon be in full operation, as they have plenty of ore on hand. The Eureka Tellurium mine is shut down, and the directors of the same are awaiting for the spirits to come forward with the wherewithal to resume operations.

ATTACHED.—*Redding Free Press*, May 30: The Ottawa reduction works on the Shasta road have been attached and the plant is for sale cheap. The failure of the enterprise is due solely to the "soap" process introduced by a man unaccustomed to mining, and does not in any manner reflect discredit on our mines.

GOOD ORE.—The Conner mines near Middle

creek, recently bonded by Biegle, Bugbee and others, are producing some excellent ore. Specimens of quartz submitted to our inspection were very rich in coarse gold. Monroe Thompson, owner of the valuable Thompson mine near the Swasey place, on the Igo road, will commence operations in a few weeks. This week he shipped a quantity of ore to San Francisco to be tested.

Sierra.

YOUNG AMERICA.—*Mt. Messenger*, May 30: Word has been received from Sierra City that good ore has been discovered in the Young America quartz mine. The rock is said to be good \$15 rock. It was discovered at the point where No. 4 tunnel taps the ledge. A chute was raised at this point when first reached, but was only put up a few feet. Since A. C. Busch has been there during the past two weeks, he ordered the raise put up higher, and within a short distance the good rock was found.

FIR CAP.—P. R. Gardner was down from the Telegraph gravel mine at Fir Cap, on Sunday. They had nearly finished repairing the old tunnel, and will soon strike out into virgin ground.

PHENIX.—Five men are now at work at the Phenix mine, and there is every indication that the claim will prove a very extensive one. There is but little doubt but that a mill will be put up this summer.

POKER FLAT.—T. C. Corlett reported times livelier than for some years past, at his mining camp. The gravel in Mr. Corlett's drift claim yielded an average of \$5 a carload this season. The last day the boys worked Mr. Corlett panned out \$10 to the pan. His largest nugget weighed a little over two ounces. The fineness is 901. Patsey O'Donnell, John Frazier and Jno. W. Clark, who have been prospecting on the East Fork of Canyon Creek, about two miles northeast of Poker Flat had a clean-up of about 11 ounces. One piece was valued at about \$17.50. Mr. Rouse is building a dwelling at the Carney quartz mine, at the head of Jim Crow Canyon, in place of the one destroyed during the heavy winter of 1889-90. As soon as he can get lumber, he will repair and start the quartz mill.

Siskiyou.

CALLAHANS.—*Cor. Siskiyou Telegram*, May 30: The vicinity of Callahans is as good a district for the thorough miner as any in the county. Because we have had one or two failures in quartz mining, it is no indication that there are no good quartz ledges here. Some of these days good mines will be found here but not by the faint hearted prospector.

HENLEY.—Water is getting scarce for mining purposes, and the miners are making preparations to wash up and it is hoped that all will be well paid for their labors. Jilson & Co. are driving their main drift tunnel day and night. This tunnel will soon be on hedrock. Black Diamond Co. of Hornbrook expects to have the diamond drill here soon and commence to drill through the sand rock to get blue gravel. This is a good move to prospect our deep mines. A. Harvey has received the lumber for his big reservoir. Several men from below are here looking over our mines.

S. H. MINE.—Summerville is situated on the south fork of Salmon river, about ten miles from its source and 20 miles from its junction with the north fork, known as the Forks of Salmon. The S. H. is a hydraulic mine with four giants of different sizes; the largest has a five-inch nozzle, carries a thousand inches of water with 350 feet fall. The flumes are three feet wide by three feet deep, with a grade of six inches to twelve feet. No derrick is used here, everything goes through the flumes. The bedrock is granite and the surface is easily piped off, which saves cleaning by hand. All races and bedrock cuts are made with the pipes. Several acres of hedrock is cleaned each year.

Tuolumne.

PLATT & GILSON.—*Sonora Democrat*, May 30: Mr. A. Trittenbach, superintendent of the Platt & Gilson mine, informs us that a working force of ten men were put in the mine this week, to drift 100 feet to the 400 foot level.

DUTCH.—Twenty-six tons of rock from the Dutch mine, situated at Quartz Mt., was crushed in the App mill last week and yielded \$3712. The owners, Louis Lucas and the Fitzgerald Bros., are satisfied that they have a valuable property, as the vein increases in size as depth is attained. Mr. John Sevenoaks, who has for many years been prominent in mining business on the Pacific Coast arrived in Sonora this week. He will remain here several days inspecting the mines of the county. His special object is to examine the Badger mine with a view to purchase by himself and associates.

GOLDEN GATE.—An extension of the Golden Gate mine, situated on the east side of that mine, and owned by Chas. Richards and Dick Phillips, gives great promise of developing into a fine paying sulphure mine. Ore from the mine, which contains a large vein, gives encouraging results. The boys are laboring under a disadvantage, not having the required capital necessary for the full development of the mine, but if it could be tickled with a little coin, we opine that soon the stamps of another mill would be chiming in with those of the Golden Gate on ore of a similar character.

NEVADA

Washoe District.

ALTA.—*Virginia Enterprise*, May 30: Five stamps of the mill are crushing ore from the old reserves between the 900 and 700 levels.

OVERMAN.—Are running but one compartment of the shaft as yet, but expect to start the other as soon as repairs to the shaft are finished.

YELLOW JACKET.—Are extracting about 200 tons of gold-bearing rock daily from the 1300 and 1400 levels, and about 40 tons of gold and silver-bearing ore from the upper levels.

SCORPION.—The joint East Sierra Nevada north drift from the 900 level of the Union shaft was advanced 25 feet, making its total distance 67 feet from the shaft; the face is in porphyry and clay.

SIERRA NEVADA.—630 level: West crosscut No. 1 from the northwest drift, 571 feet from the shaft, has been advanced 31 feet; total length, 448 feet. The formation is very tough.

CHOLLAR.—The south drift, 1400 level, from the north line, is out 132 feet; face in hard porphyry. The winze in the joint east crosscut, north line, 1400 level, is down 18 feet; the bottom is in porphyry. Extracted and sent to the mill the past week 543 tons of ore, worth, as per battery samples \$24.50 a ton.

POTOM.—The winze is down 117 feet below the 1400 level; the bottom is in porphyry and streaks of quartz. The south lateral drift from the winze station, 1300 level, is out 254 feet; face in porphyry. The south lateral drift from the Chollar incline, 1100 level, is out 196 feet; face in hard porphyry.

EXCHEQUER.—The east crosscut on the north line, 600 level, is out 218 feet, face in porphyry.

ALPHA.—The south drift, 218 feet east of shaft, 300 level has been repaired 36 feet. West crosscut, 100 feet north of the shaft, 500 level, is out 659 feet; face in hard porphyry.

SILVER HILL.—The southwest drift, 50 level, is out from shaft 60 feet; face in soft porphyry. South crosscut, 160 level, is out from winze 550 feet; face in hard porphyry.

NEW YORK.—North lateral drift, 600 level, is in north of shaft 222 feet; face in porphyry. North lateral drift, 1100 level, is out north of shaft 509 feet; face in low-grade quartz.

WARD COMBINATION SHAFT.—The south drift from the 1800 station is out 40 feet.

SIERRA NEVADA, MEXICAN AND UNION SHAFT.—West drift from the shaft, 900 level, is out 264 feet, making 52 feet during the week; the face is in hard porphyry.

UTAH.—Incline winze has been sunk 31 feet; total depth, 95 feet, continuing in porphyry, clay and quartz of low assay value.

SEG. BELCHER.—On the 600 level the west crosscut from the south lateral drift is out 72 feet. It is still in soft porphyry.

CON. IMPERIAL.—We are still following up and taking out small streaks of ore on the upper levels and prospecting in and around the old stopes, where we find some fillings and bunches of ore of fair grade, which is being shipped to the Brunswick mill for reduction.

BELCHER.—The south drift from No. 2 crosscut on the 200 level is now out 310 feet. The face is in a mixture of clay and low-grade quartz. The north drift from the main west crosscut from the shaft, 300 level, is out 186 feet. The face is in porphyry and low-grade quartz. The east crosscut from the north lateral drift on the 1500 has been advanced 13 feet during the week. The face is all quartz, assaying from \$2 to \$12 per ton.

CHALLENGE CON.—The joint Confidence and Challenge west crosscut on the 600 level is out 48 feet, 10 feet having been made during the week; the face shows quartz of no value. Joint Confidence and Challenge north drift on the 1100 level is in 273 feet, 20 feet having been made during the week; the face being in porphyry.

CROWN POINT.—The east crosscut from the south end of the 350 slope on the eighth floor has been advanced 26 feet during the week and is now out 32 feet. The face is in a mixture of porphyry and clay. The east crosscut on the 1000 level has been extended 26 feet since last report, and is now out a total distance of 130 feet. The face is in vein material composed of clay and quartz.

HALE & NORCROSS.—On the 1400 level the winze from No. 3 east crosscut is down 120 feet, the bottom in porphyry. The joint winze in No. 5 east crosscut on our south boundary is down 10 feet. We have put in a small hoisting engine at the top of this winze and have the same running, which will greatly facilitate the work of sinking. On the 1500 level the north and south lateral drifts from the station are each advanced ten feet. The formation in these drifts is porphyry.

SAVAGE.—We have hoisted 586 cars of ore from the 500, 750, 800, 900 and 1000 levels. Shipped to the Mexican mill 541 tons and milled 630 tons; average battery assay, \$17.25. We have bulion on hand amounting to \$224,488.06. On the 750-foot level we are extracting rich ore. On the 950 level the winze started 180 feet north of our south boundary is down 40 feet; the bottom is in porphyry. The south upraise from this level has been carried up 59 feet; from the top of this upraise we have started an east crosscut and advanced the same 15 feet in quartz and porphyry. On the 1100 level the west crosscut opposite the east crosscut from the north drift was advanced 35 feet; total length 60 feet; we have stopped work on this drift and resumed work in the face of the north drift. The north drift, 1400 level, was advanced 7 feet, making its total distance north from the east crosscut 70 feet; we are stopping fair ore from this drift. We have started an east crosscut from the end of this drift, and advanced same 12 feet.

ANDES.—On the 420 level, east crosscut from main north drift was advanced 20 feet; face in quartz and porphyry. During the week this crosscut has been passing through quartz that yields low assays. East crosscut from south drift was extended 13 feet, face in quartz.

OCCIDENTAL.—Extracted pay ore from the 300, 400 and 450 levels. South drift from No. 1 upraise, 500 level is in 91 feet, face in low-grade ore. North drift from same point is 106 feet; face in quartz and porphyry. The upraise from south drift, 600 level is up 24 feet; top in pay ore. North drift from No. 2 winze, 650 level, is in 372 feet; face showing ore of some value. South drift from No. 1 winze, 750 level, is in 101 feet; face in low-grade ore.

Ely District.

PURCHASE DECLARED OFF.—*Pioche Record*, May 30: The people of Ely are once more keenly disappointed in the hope of a speedy revival of general business there, the proposed purchase of the Joanna mine by the syndicate of Montana mining men, reported last week, now being declared off. The immediate cause of the failure is the litigation hanging over the property, which the purchasers were assured was ended, but which on examination was found to be still alive. They expressed themselves as very well pleased with the property, but declined to assume or risk any litigation. The claim against the mine is made by Mrs. Josephine Wolcott, of San Francisco, who says she is entitled to a half interest, through furnishing Watson, the presowner, with a grub stake of \$5000 to prospect with, she to own equally with him in all properties located. Watson says Mrs. Wolcott was to share only in such copper mines as he might locate and in no others; that she is interested in all such claims. Last year Mrs. Wolcott sued for half the Joanna property and the suit was dismissed on a technical point in the district court at Ely. Mrs. Wolcott, however, is seeking to have the judgment of dismissal set aside and for a trial of the case on its merits, and until it is settled uncertainty will attach to the Joanna title. All who have examined the property during the past two years report it as possessing great merit, and its active working is regarded as

certain to develop the whole district and revive the drooping interests of that section, as other good claims lie close to it. The people of Ely are greatly disappointed at this second failure of a sale, and we understand some are leaving the place in disgust, under the belief that nothing will be done there for an indefinite time.

Hawthorns District.

LAPANTA.—*Walker Lake Bulletin*, May 29: During the week the main northeast drift above the tunnel has been extended eight feet. Same has been stopped for the present and an upraise has been started on the ore 25 feet back from the face. As indicated in the last report, 10 inches of \$100 gold ore has been encountered in the incline below the tunnel, and a drift has been started south on this ore from the point of discovery.

PANLICO.—The lessees still continue to extract good ore from the north tunnel and the stopes at the long incline, and some rich ore has been encountered in the incline below the location tunnel.

CENTRAL.—Still stopping both ways from the incline above 75-foot level, and sinking incline, which is now down 150 feet on vein.

MOUNTAIN KING.—The south drift from the tunnel has been extended 25 feet, and a crosscut run through the ledge. Same shows very strong. The main tunnel is being run ahead to cut the hanging-wall vein.

HARTFORD.—Principal work done in this claim during the week has been stripping the vein at the south end of the claim.

BEACON.—Drifts are being run each way from the incline and stopes being started on the ore.

CAPITAL.—The drift from the crosscut is being extended on the vein, showing the same character of high-grade ore in the face.

GOLD BAR.—The incline winze is down 55 feet, the vein showing very strong, and a drift has been started north from the bottom, following the vein.

DICTATOR.—Still engaged in opening the copper and silver vein on the surface.

CONFIDENCE.—The incline from the northwest from the main upper drift has been extended 15 feet, the vein going down at an angle of 25 degrees and showing very strong. Considerable second-class ore has been sacked during the week.

FAIRMOUNT.—The main south drift has been extended 14 feet during the week. The ore still holding in the face and getting stronger. A stope has been started above this drift which is producing considerable 150-ounce ore.

CHALLENGE.—A winze has been started below the tunnel showing a good-sized vein, the grade of the ore being about 60 ounces.

WAR EAGLE.—Still extracting ore from the stopes.

IDA.—A very nice body of ore has been exposed in this mine in the winze below the tunnel. A drift has been run east on the same 50 feet below the tunnel, which shows the same character of high-grade ore.

Pioche District.

THE NEW SMELTERS.—*Pioche Record*, May 30: Work at the new smelter is progressing fairly well. Stone masons are busy putting in substantial dust chambers and flue, and the work of throwing up the grade to the ore bins continues. Foundations for two ore bins are ready and 45 feet of the main building is up and covered in. When finished this building will be forty feet wide by 120 feet long. The south half of the building will not be raised until the boilers and stacks are placed which will be done as quickly as possible. A small boarding house is finished ready for occupancy and an office and scale room is in course of construction. The course of the projected tramway line from the works to west point and the Day mine is altered so as to run almost straight from the works to the point instead of running up and skirting the foot hills just west of town. This it is found will shorten the line somewhat and make the grade better.

Silver King District.

TO CONSOLIDATE.—*Pioche Record*, May 30: John F. Cupid, County Recorder of White Pine county, came in by private conveyance Monday evening and remained over Tuesday, returning Wednesday by way of Silver King district, at which place he is interested in several mining claims. A movement is now on foot to merge all the claims in that district owned by the Wheatly brothers, Cupid and others, some ten in number, and make one sale of the whole. Only one or two owners remain to be seen about the matter, and it will probably be done, when we may look for something far above the average there, as ore is plentiful, though mostly low grade.

Taylor District.

DESERTED.—*White Pine News*, May 30: We made a brief visit to Taylor Tuesday in company with J. B. Simpson, C. B. Wadleigh, Major Trece, Fred Clark and F. X. Murphy, to attend the funeral of Col. Fitton. We found the place almost deserted so far as visible signs go. Still, there are a number of people living there yet, and when the Monitor miners come out and the other residents get together the place takes on a livelier appearance than any one would think at first glance. One thing about Taylor is particularly noticeable for a nearly deserted place, and that is the good condition of the vacant buildings and sidewalks. They appear in just as good condition as when vacated nearly three years ago.

BONDED.—The Argus mines in Taylor are said to have been bonded by A. C. Cleveland, and the people of that town are in hopes that a California corporation will soon take hold of the property and resume operation thereon.

Tuscarora District.

NAVAJO.—*Times-Review*, May 29: The 350-foot level stopes are looking well. Everything running as usual.

DEL MONTE.—Joint west crosscut, 3d level, has been extended 24 feet. Joint raise from same crosscut has been connected with north drift on the 2d level.

NEVADA QUEEN.—South drift from east crosscut, 4th level of Commonwealth, advanced 15 feet; still in vein formation. Nineteen tons of ore worked at Union mill; average battery assay, \$25.79 per ton.

BELLE ISLE.—West crosscut from the south drift, 350-foot level, extended 12 feet in favorable formation. The men have been put to drifting north and south on the ore cut last week, progress 15 feet. The

south drift shows over two feet of ore, most of it being very high grade.

COMMONWEALTH.—North drift from east crosscut has been extended 10 feet on the vein. Raise started and up to feet, showing a streak of fair-grade ore; picked sample assayed \$262 per ton. South drift extended 15 feet. Forty-three tons of ore worked at the Union mill, battery assay, \$216.42. Forty tons of ore sent to the concentrating plant.

NORTH COMMONWEALTH.—First level: Stopes continue about the same. Seventy-six tons first-class ore worked at Union mill, battery pulp assay, \$198 per ton. Shipped bullion valued at \$30,266; crude bullion on hand about \$15,000. Will ship again Monday.

NORTH BELLE ISLE.—North drift from Belle Isle 450-foot level extended 22 feet. No. 1 winze, same level, extended 11 feet, showing some good ore; water very strong. South drift from No. 1 east crosscut, 400-foot level, extended 16 feet. North drift, same place, extended 9 feet, face showing some good ore. The stopes above these drifts are improving. No. 2 east crosscut, same level, extended 30 feet. South drift, 500-foot level, extended 8 feet. The stopes from No. 4 chute, 600-foot level, are yielding some very rich ore. Broke 7 cars of first-class and 51 cars of second-class ore. The Union mill has crushed about 50 tons of ore, assay value \$250.

White Pine District.

PROSPECTING.—White Pine News, May 30: Parties in from Hamilton tell us that Supt. Read intends to work 25 or 30 men this summer prospecting in the Eberhardt tunnel. It is also said that the indications for getting rich ore are very good.

ARIZONA.

DIAMOND JOE.—Mohave Miner, May 30: Nearly two car loads of beautiful copper-silver glance ore from the Diamond Joe mine, near Cedar, was worked at the sampler last Tuesday. The ore is rich in silver, copper and lead, and returned considerable money to the owners. The mine never looked better than at present and the prediction is made that it will be one of the steadiest producers in the county, as the mine is opened up in a shape to work. Quite a number of men stopping out ore and still continue prospecting for more, a thing that is seldom done in Mohave county.

SCHUYLKILL.—Cross Bros. are preparing to commence work on the Schuykill mine at Chloride. The Schuykill is one of Chloride's oldest locations and a smelter was erected on the ground years ago, but owing to imperfect knowledge in the art of smelting the smelter was not considered a success. Thousands of tons of rich lead ore have been shipped to the various smelters in New Mexico, Colorado and Southern Arizona. The cost of hauling and shipping cut an immense hole in the value of the ore, but at the same time it paid much more than the shipping expenses.

TIN AND ZINC.—Tombstone Prospector, May 26: The discovery of a great vein of almost pure zinc near the river and only 30 miles above Yuma is of great importance. A vein 60 feet in width and a half a mile in length with ore that runs from 75 to 90 per cent of zinc is not met with every day. Another very important discovery lately made on the borders of Yuma Co., is that of two veins of tin, each of which is about three feet in width. The assays made, show the ore to be of a high grade. Competent judges and experts believe that this is one of the most important discoveries ever made in western Arizona.

NOTES.—Prescott Courier, May 29: J. B. Kelly's team is constantly engaged bringing in ore from the Wren and Blue Dick mines, Hassayampa district. Catocin, at a depth of 111 feet, is eight feet wide and very rich. Ore is shipped from the Prescott ore works. J. O. Floyd, of Turkey Creek district, is taking out good ore. So are Reed & Watson. F. Scopel works ore from the Gen. Crook ledge in an arrastra, pays his way and has a snug bank account. Lots of ore from the Belle and another Big Bug district mine are at the sampler. Three furnaces are running at United Verde. Fifteen large teams hauling coke, bullion, etc. This is the camp to which a railroad is being constructed. Blue Dick is sending in good ore. Capitalists have made an offer for the mine. John S. Jones has started work on his dam in Big Bug district. The dam will be 110 feet at top; 20 feet deep; 'twill give him water to run his mill, etc. Following facts concerning the Yuma copper mines are learned from C. W. Culver, who came from there a couple of days ago: They are owned by rich men of St. Louis; consist of 32 claims; opened by shaft, 450 feet; another, 350 feet; 4000 feet of tunnels and drifts; 50,000 tons of ore in sight; carries gold and silver in moderate quantities. There are two bored wells; the deepest is 800 feet; both contain considerable good water. More water is being piped from a spring in a mountain. A 50-ton smelter will be started running about the first of next month. Two more smelters, of same capacity will soon be set up. Tramway from mine to smelters is being made. The camp is 75 miles from Prescott; 95 from Phoenix. The company will give \$150,000 or \$200,000 to any company that will construct a railroad on the Date creek route.

BRITISH COLUMBIA.

TRAIL CREEK DISTRICT.—Nelson Miner, May 29: A district may have good indications for mines, but unless the advantages of the district are brought to the attention of prospectors and investors but little headway will be made. That Trail Creek district has good indications of mineral is not now disputed, and no man can well dispute that to E. S. Topping is due much of the credit for getting mining men interested in the district. Mr. Topping has been untiring in his efforts, and he has been rewarded by selling the Le Roi to a Spokane company for \$25,000, not in Spokane real estate but in good money and bankable paper. He arrived at Nelson this morning and reports the camp as quiet, but that by the middle of June operations will have made a start. The company that purchased the Le Roi also bonded the Center Star, the Idaho, the Harvey, the Pride of Trail Creek, and the Chief of the Mountains, and expects to have a force at work on them by the 15th of June. They got a return of \$72 in gold and 14 per cent copper from an average sample taken from the Le Roi, and are well satisfied with their investments. The ore in the claims on the south side of Trail creek has changed in charac-

ter and is now almost entirely galena. Of these claims Hoover's Lilly May is probably the best known. From a picked specimen of it an assay of \$500 in silver was obtained, an average sample assaying \$167. The surface ore of nearly all these claims carried gold and copper; but now little gold is obtained and the copper is replaced by galena. John H. Reed sold the Blossom to Mr. Topping a few weeks ago. Since purchasing it Mr. Topping has run a tunnel in on the ledge 32 feet. The face of the tunnel shows four feet of ore, from which assays of \$47 in silver and \$7 in gold have been obtained. Several new locations have been made this spring. Jack Buchanan making one which promises well. From 60 to 75 men are in the camp.

CHANGED OWNERS.—The Boulder hydraulic claim on 49 creek has changed ownership, H. F. Keefe, D. McGillivray, R. G. Tallow, and R. C. Ferguson purchasing it from A. L. Davenport, M. C. Monaghan, the Barker Brothers, N. Riopell and J. P. Lamotte. The consideration is said to be \$2000. The claim is believed to be a good one, and if worked systematically will no doubt yield good returns on the investment. The ditches are being cleaned out, and operations will be commenced in earnest next week. Vancouver men are thus bound to get in and make a killing in the lake country.

ANOTHER GOOD FIND MADE IN GOAT RIVER DISTRICT.—That "Jap" King's Alice is not the only prospective mine in Goat River district is evidenced by the samples of ore exhibited by C. C. Sproule and George Long from a claim of recent discovery. From three assays made, returns of over \$100 to the ton in silver were obtained. Besides silver the ore carries large percentages of lead and some copper.

ABOUT 100 MEN ARRIVING WEEKLY.—About 100 men a week are arriving in the lake country. A large percentage of these men are miners and prospectors, and hail from every state and territory in which mines are worked. One camp over on Rover creek, near the late galena discoveries, is made up principally of arrivals from Idaho, thirteen of the number being Cœur d'Alenars.

COLORADO.

SILVER AGE.—Idaho Springs Gazette, May 30: They have struck a four-foot streak of ore in the 6th level of the Silver Age. The rains lately have made the road impassable and they have been unable to mill any ore for two weeks. There are 100 tons already sorted up at the mine and 120 tons broke in the mine and not hoisted out. The placer mine which is being worked at the mill looks as though it would prove a bonanza. Two men are taking out 1/2 oz. per shift now and bedrock sloping off toward the mountain, which proves that they have not yet struck the deep channel. With expenses on high bedrock, the deep channel ought to pay largely.

DAKOTA.

GALENA.—Deadwood Pioneer, May 27: There are a number of properties in this camp that are now being worked, and many others that are only awaiting the advent of a railroad, when operations will be commenced at once. This is pre-eminently a low-grade camp, ten tons of ore not averaging over \$30 where one ton goes \$80 or \$100. Consequently it will not pay to haul long distances, ship to smelters and give up an exorbitant price for reducing.

AN IMPORTANT FIND.—A new find of 'free milling ore has been opened up within the city limits that will create a sensation. Experts will report, and a free milling plant will be the next great sensation.

SCOTIA.—Supt. Cassels, of the Scotia, is somewhat jubilant over the recent strike in that property, and thinks that it will prove to be a find of magnitude. Five stamps of the Monitor mill are now running on the ore, which goes \$6 per ton.

MONITOR.—Indications at the Monitor mine are favorable for a resumption of dividends at no distant date. The quality of the ore is steadily improving and as the roads are in good condition, the expense of hauling the ore from the mine to the mill is greatly lessened.

IDAHO.

ATLANTA.—Cor. Idaho Statesman, May 30: Atlanta is patiently awaiting the revival of interest in this long-neglected camp, which it is confidently expected will occur during the coming summer. The wished-for transfer of the Atlanta Hill property seems now to be an assured fact and the transfer papers are all on record. It is expected that Mr. Miller will add more stamps to the Taboma mill and work the mine more extensively than it has heretofore been. Mr. Oglesby has lately arrived from Boston, Mass., and is preparing to start up the Big Lode mining property. Mr. Oglesby intends running a tunnel to tap the ledge. Said tunnel will be about 400 feet in length and three shifts will be worked. The company already has a fine mill just below where the drift will be, and as soon as the ledge is reached will be able to go at once to extracting and crushing. The Buffalo mill is at present running on ore from the Buafflo mine and still has about a month's run ahead. The property was taken on a lease last fall, when the company shut the mine down, by a party of miners consisting of a dozen or more, and they have been working it ever since. They have out 400 or 500 tons of rock, which, according to the battery samples is good. No. 1 rock, and each of the leasers will clean up quite a little pile. Mr. Geo. Tims has had quite a number of men working for him all winter and is only awaiting the starting up of the Taboma mill to have his rock crushed, of which he has quite a large amount. Messrs. Irwin and Shultz also have out quite a run of first-class ore which they are waiting to get crushed. Water having been very scarce here this season not much has been done in the way of placer mining. Mr. R. B. Brown has been taking out ore on the Atlantic hill as has also Messrs. Wm. and Lee Abbott and Louie Frankey on a bar below the town. Mr. Prey and son were mining on their claim as long as the water lasted and did very well. At the Bar everything is working along smoothly and all of the different properties are slowly increasing their working force. The old reliable Elmore never looked better, and the same may be said of the Vishnu. They are both working a full force of men, and the stamps are kept working day and night. The Ophir has lately started up under the

general management of Mr. Boyd, with Frank Lester as foreman, and is looking fine. The Wide West at Red Warrior is increasing in size and richness every day. Besides these there are a number of minor properties working, all of which are looking extremely well. Adam Gottsch has a five-foot vein of No. 1 milling ore on his Richmond claim which gets better and richer as he advances on the ledge. Jake Ruter has several men employed on a fine prospect above the town on Bear creek, and the Queen of the Hills, owned by Pierson, Adams and Ahernson, never looked half so well as it does at the present time, and as it has always been one of the finest prospects in the camp that, I think, is saying a good deal. From the necessarily imperfect and incomplete account of the above-mentioned properties it will readily be seen that everything points to the continued and rapidly increasing prosperity of Atlanta, the Bar, and indeed this whole section of country adjacent to the two camps.

MONTANA.

IN THE TOWNSEND DISTRICT.—Townsend Messenger, May 28: The Silver Star mine has an incline shaft 124 feet deep, from which has been taken numerous carloads of ore. There is now between three and four carloads of first-class ore at the mine ready to be and which will be shipped to Omaha in a few days. The lode is four feet wide and the average assay is \$50. The work of running levels from the bottom of the shaft will be prosecuted with three shifts, and it is expected that the mine will be in shape to produce several carloads a week by the 1st of July. The company, which is a close corporation, has abundant capital, and the management is in the hands of good business men who are determined to thoroughly develop and work systematically. It has been surveyed and the proper application for a patent initiated.

THE DAKOTA MINE.—Neihart Herald, May 28: The Dakota mine is generally regarded by expert mining men as one of the finest properties in the State, and indeed it may be said that there are few other mines in the Rocky mountains that have the showing of ore for the amount of development done. It is estimated by conservative figures that there are 300,000 tons of ore exposed in the workings, which consist of three tunnels and a shaft, all of which will not amount to more than 1500 feet of development. The Lady Shalotte is the extension of this enormous vein and is one of the properties of the St. James Con. Mining Co. The intention is to let a contract to sink on this lead in the next few days, and as the shaft is now at a depth of 16 feet, in six feet of ore and the footwall has not been found, it is fair to presume that some grand results will obtain from further development of this property.

BOSTON AND MONTANA'S NEW WORKS.—Great Falls Industrial, May 28: J. W. Cornelius, the gentleman who has all the contracts for putting up the buildings at the Boston & Montana Works, says that he has now over 300 men at work and that the buildings will be pushed to completion just as fast as men are able to do it. In his opinion the works will be finished this year and be in running order by January 1, 1892. The fact of the railroads forging ahead to the Barker and Neihart district makes it imperative on the part of the management to push work as rapidly as possible in order to be ready for the great influx of ore that will come in when the railroads once tap these districts. At a low estimate the Boston & Montana Works will employ 1000 men.

NEW MEXICO.

RICH ORE.—Pinos Altos, May 29: The Dimmick Brothers are taking out three classes of ore. The first class runs \$18,000 to the ton; second \$10,000 and third \$5,474. If there is anything in this country that can beat their's in the way of a mine it is not yet known. And that little property is one of the many rich claims in the Pinos Altos district. The Climax, the south extension of the Silver Cell, is down 50 feet between well defined walls. At the bottom of the shaft the lead is more compact and valuable than any time since discovery. At 100 feet a drift will be run north to connect with the Silver Cell, when unless all signs fail, the two will meet in a silver ball that will put the bridal chamber "to bluse." The Silver Cell is now down 65 feet, all in metal. At the bottom of the shaft the lead is more compact and valuable than ever, demonstrating beyond a doubt that it is not, as many supposed, simply a pocket. The owners do not propose to drift until down 100 feet. They have taken out about \$10,000 while sinking, and should they desire, could take out ten times that amount by stopping from the shaft alone. The Alice mine, owned by Jim Woods, is being worked by Fritter and Brakehill. These gentlemen are taking out ore that may be classed simply as lead. At this writing there appears to be no limit to the metal, and unless all signs fail the lesses have a bonanza.

UTAH.

PARK NOTES.—Park Record, May 30: Owing to the late spring and the slow manner in which the snow is leaving, many claims are still idle, which will be actively developed during the coming summer. The snow is still deep enough in places to retard operations, and many miners are working under the disadvantage of short supplies, both as regards necessities of life and mining supplies, as but little hauling can be done. The greatest drawback at the present time, however, is trouble from surface water, which is bandicapping almost every property visited.

WASHINGTON.

TOUGHNUT AND HOMESTAKE.—Okanogan Outlook, May 28: The statement of Col. Wallace, in the Spokane Review, that John W. Mackey and others, of Comstock notoriety, have bonded the Toughnut and Homestake mines in this district and will commence mining operations here on a large scale, naturally excites a great deal of enthusiasm, and speculation is rife as to what mode of operations they will pursue.

BLACK BEAR AND WAR EAGLE.—The War Eagle and Black bear mill site presents a scene of bustling activity. A force of from 15 to 20 men are pushing work on the water ditch which will be completed in a few days. A short flume will then have to be built to carry the water from the ditch to the

mill. Lockwood's sawmill is busy cutting lumber for the mill and a corps of surveyors are laying off the site.

HIDDEN TREASURE.—Wm. O'Neill has sold a half interest in the Hidden Treasure claim to F. W. Wittenbrock & Co., of Spokane, for \$3000.

WORKING IN THE COAL.—Wm. Stillwell, Geo. Stillwell and Geo. Heller started this morning with four pack horses loaded with provisions for the Melbow. They expect to do considerable development work on their coal properties this season.

THE LONE STAR.—The Lone Star shaft is rapidly approaching the 400-foot level, and its progress is being watched with a great deal of interest by all who are identified with the development of mines in this district. Allen C. Mason and Henry Lawrence for five years have been pushing development work almost without intermission, and now have about 1800 feet of tunnels, drifts and shafts. A depth of 350 feet has been reached in the main shaft, and the result shows that the ledge has been gradually increasing in size and the amount and quality of ore has continued to improve with every foot of depth gained below the surface. What was originally a 16-inch vein of comparatively low-grade ore, at a depth of 345 feet (before the present work was begun) had developed into a six-foot ledge of almost solid ore. The grade of the ore has also improved in nearly the same proportion.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

WEEK ENDING MAY 26, 1891.

452,903.—DOOR-SECURER—N. Cosman, Fremont, Wash.
452,946.—GAS GOVERNOR—F. Ellis, S. F.
453,042.—FRUIT PITTER—W. C. Evans, Oakland, Cal.
453,045.—HINGE SINKER—W. H. Gutzman, Berkeley, Cal.
453,117.—CAR AXLE BOX—D. B. James, S. F.
452,947.—DOOR-SECURER—W. B. Morris, Seattle, Wash.
452,948.—STRAW SEPARATOR FOR THRASHERS—E. H. Nicholson, Santa Maria, Cal.
452,942.—AIR BRAKE SYSTEM—Wm. W. Slater, Oakland, Cal.
453,165.—FAUCET—C. P. Smith, San Diego, Cal.
453,095.—TRAMWAY—J. T. Vinion, Spokane Falls, Wash.
452,818.—SANITARY PLUMBING—F. A. Weinshank, Los Angeles, Cal.

The following brief list by telegram, for June 2 will appear more complete on receipt of mail devices:

California—San Francisco, James B. Stetson, J. Hammond, W. L. Holman, J. W. Harris, cable gripping mechanism; John T. Smith, W. Copeland, tanning connection; John A. Larsooth, mechanical ledger; Emery L. Nichols, governor and valve movement for gas engines; San Diego, Elmore Stewart, car coupling; Santa Cruz, Hiram M. Hamore, non-heat-conducting composition; Fresno, James Porteous, raisin and fig press.
Oregon—Salem, Michael J. McKinnon, tire tightener; Taylor, Geo. W. Rowley, cable clamping device.
Washington—Seattle, John M. Frink, J. Readman, logging truck; Colfax, Legrand D. Harding, shoe for deformed feet; Lacouner, Peter E. Frostad, rudder for boats.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

AIR-BRAKE SYSTEM.—Wm. W. Slater, Oakland. No. 452,942. Dated May 26, 1891. This invention relates to an improved signal for use on railway trains and means for operating the air-brakes thereby. It consists of an electric conductor extending through the train of cars, means for coupling the ends of the conductors at points where cars are coupled together, a means for completing the circuit from any point in the train, and the mechanism whereby the completed circuit is caused to act upon an electro-magnet and through it to open air-valves, so that the engineer from his station may at any time test the connections and be sure that the electrical circuit and the air-pipes have been properly coupled in making up the train, and also to operate the air-brakes, while from the rear or any other portion of the train the engineer may be signaled at any time by completing the circuit. The usual method for making connection between the front and rear end of the train is by means of a cord extending through the train from end to end. In practice it is found difficult and almost impossible to operate this cord through a long train when it is often broken in the attempt to use it. By Mr. Slater's device electrical conducting-wires are used instead of a bell-cord and they are so arranged that a complete circuit is made between any number of cars. Stops may also be made by means of the rear valve mechanism so that the rear brakes are set first and act as a drag from behind. This avoids the irregular end motion of the train which results from the opening and closing of the engineers valve when that is used and which unavoidably causes a jerky motion when coming to a stop.

DOOR SECURER.—Wm. B. Morris, Seattle, Washington. No. 452,947. Dated May 26, 1891. This is a novel device for fastening doors and which may be used separately or in addition to and in conjunction with the ordinary locks and fastenings. The construction is such that a traveler may carry the device conveniently in his pocket so that he may apply it to the door of any room which he may be occupying. When applied to the door it will be impossible to force the door open without tearing the fastening out of the casing or in some other way breaking or destroying it.

The mine-owners at Mullan, Idaho, have organized in opposition to the Miners' Union.

SCIENTIFIC PROGRESS.

Prof. Swing on Immortality.

To believe well in a future beyond, it seems essential that we should make the assumption of spirit as a starting point, and then the whole material world becomes the servant of the spirit; but if, with Huxley and Darwin, we begin with the assumption of matter, there seems nothing to throw us across the dividing ocean, and we must remain on the shore of dust, and hence death; for, move to and fro as material does, from wild rose to full-leaved rose, from ape to man, it always brings us at last only the dust. There is no immortal rose, however full-leaved it may become. Death is its destiny. To get over this tomb of roses and of man, it is essential that a spirit be assumed; a God, an essence differing from the vital action of the heart or of the roots of the wild flowers. In this study of man, alter we assume that he possesses a spirit, the text enters with its single thought that God is not a God of dead souls, but of living ones. There is no manifest reason for supposing a soul made in such a divine image to be only an ephemeral creature, going quickly to nothingness, thus making God the Father of the dead rather than of the living. All the reasons for creating such a being as man remain for continuing his existence. If, when the Creator had formed such a universe as lies around us here, of which our system is as a grain of sand upon an infinite shore, He finally concluded to make man a race to inhabit one or more stars of the universe, a race in the divine image, a human life of a few years would seem wholly unworthy of such a boundless material realm; for we cannot master its truths nor taste happiness in any three-score years' career. Your children have shown their divine nature, have spoken a few words, have rejoiced in a few springtimes, and have gone hence, leaving you heartbroken. A brief career is thus not in harmony with the immense universe in which this life begins, and of which man is unquestionably the highest order of beings.—*American Spectator*.

A more philosophical theory to our thinking would be the assumption that both spirit and matter are eternal and co-existent—as positive and negative, intelligent and inert. That spirit which we call God, through its intelligence, moved upon matter, and matter thus became the "servant of spirit." With such an assumption there is no "dividing ocean" to cross; moreover, it is as easy and quite as philosophical to assume the two existences as the one. All subsequent events might follow from laws ordained by spirit, or by evolution, as you please. Matter may move to and fro "from wild rose to full-leaved rose, from ape to man," but all must return again to dust. The rose from the wild to the full-leaved would fulfill its mission. There would be "no immortal rose, however full-leaved it may become." But alter the rose the animal, and in the fullness of time man, as the limit of evolution (creation if you please). Into man, as the crowning work of evolution or creation, spirit infused its divine or never-dying life, "and man became a living soul"—immortal in his soul existence. Its earthly covering, like the full-leaved rose, must return to dust from whence it came, but the spirit "returns to God who gave it" to continue its spirit existence through all eternity.

Matter may change its form from gas to rock, to tree, to rose, to animal, but it never disappears—it is as eternal as the spirit which acts upon it. There is a vegetable life and there is an animal life, but there is no essential difference between the vital action of the heart and the movement which sends the life-giving fluid of the vegetable from its roots to its branches.

The spirit in man, which we call soul, is a part of the original spirit which first acted upon matter in the beginning—if we may assume a beginning. That original spirit we call God. It exists everywhere throughout the universe.

The essential thing in man is his soul—his spirit life—a life which is not in the brute. The brute may think; may be affected by fear, by love, by anger; but the brute has no aspirations for the future. His thoughts do not pass beyond the present. Therein lies the great difference between man and the brute. Since it has been given to man to look for and to aspire to a life beyond the grave, there is no manifest reason why the source of that aspiration—the soul, which distinguishes him from the mere animal—should not attain its desires. Everything in reason and our aspirations points to the supposed fact that God has endowed man with a never-dying principle, which, when it throws off this earthly covering, will return to

the source whence it came, just as the body returns to the dust from whence it came.

We have assumed that spirit is intelligent. That intelligence must have been infused into man, as the climax of inert matter for a purpose. What purpose could be effected if man dies as a beast dies? The few years of his existence on earth, as is said above, "would seem wholly unworthy of such a boundless material realm," as is the universe which we inhabit. In very truth, there "is no manifest reason for supposing the soul of man, made in such a divine image, to be only an ephemeral creature, going eventually to nothingness." Such a brief career is not in harmony with the aspirations implanted within, as by virtue of the God spirit—the soul. Man is evidently the highest order of being, and for what purpose could he have come into existence, with all his possible and elevated aspirations, without it was to pass beyond this finite life to progress in a future existence, far beyond anything of which he is capable of imagining while encumbered with his earthly surroundings? W. B. E.

The Production of Heat.

The marvels of scientific discovery and mechanical invention crowd upon latter day nineteenth century folk in a manner rivaling the play of kaleidoscopic figures. One accepts, nowadays, what he sees, as his fathers did of old, but, unlike them, he is not prepared to dispute the possibility of anything within the range of conception. One of the most wonderful results of application of human reason in employing an essential element of the universe for human purposes is that described in the last issue of *Bradstreet's* by Mr. Lorin Blodgett, a well-known member of the Franklin Institute of Philadelphia.

Air as Fuel.

This is nothing else than the use of atmospheric air as fuel. Air is mixed with coal gas, as everyone knows, and with hydrocarbon vapors, and the compound when burned generates a much greater heat than if the air was absent. So, too, a powerful air blast is a great economizer in smelting and reducing ores. But the new fuel is the air itself, which in a powerful blast is directed upon an incandescent substance, say coal made white hot, pure carbon or any other materials that can be made to glow. Coal hydrocarbons or what not may be employed to give the initial incandescence, but once the blast strikes the luminous body, the utmost intensity of heat is secured, apparently by the combustion of the air, and may be maintained for an indefinite period by merely preserving the incandescence of the surface and this may be done by a slight manipulation of the surface brought to incandescence, and with some slight renewal of carbonaceous material.

ANOTHER HEAT PRODUCING CONCEPTION.—Another most extraordinary discovery is that claimed by M. O. de Clausen, a Russian engineer, who has been experimenting in London with a new stove. Finding that much free oxygen escapes with the unburned fuel from chimneys, this experimenter concluded that—contrary to the ordinary theory—less draft and higher temperature are needed in order to get perfect combustion. He secures these in a stove three feet high by one foot in diameter, lined with fire-brick. Only the lower portion of the coal burns, a very small current of air being admitted to this, and passing upward sufficiently hot to cause its remaining oxygen to unite with the carbon monoxide gas in the upper portion of the coal. The products escaping into the chimney are colorless and quite cool, and if the statements made are to be accepted, less than three per cent of the possible heat is lost, instead of the 80 or 90 per cent ordinarily wasted.

THE SUN'S LIGHT AND HEAT.—Does the sun give light and heat to the earth directly, or is heat generated by the action of the sun's rays upon the earth? is a question which has interested and puzzled many of our best scientists. The *Scientific American* refers to the matter as follows: "The sun's heat is supposed to be transferred to objects by ether waves. These are not considered to be heat, but to be capable of producing heat when they impinge upon matter. The atmosphere being attenuated and thin in the upper regions, is less heated than in the more dense portions near the earth. The heating power of the sun is also very great at high altitudes when radiating upon surfaces properly prepared to receive and absorb the heat. The nearer we approach the sun, the more powerful are the radiations or ether waves."

THE MARCH OF SCIENTIFIC DISCOVERY.—Mr. John Cox, M. A., in a lecture delivered recently on "The March of Scientific Discovery," said that although the importance of scientific discovery was recognized, it was questionable whether the influence which it exerted upon modern life was fully appreciated. He referred to the great advantages which had taken place during the present century, particularly mentioning steam and electric power, the latter being, he thought, still in its infancy. By the

aid of science all quarters of the globe had been brought in daily communication, and in every department of industry, where mere brute force was required, the labor was being taken from the shoulders of men and placed upon machinery, and great scientific discoveries necessarily brought about great social changes. In the course of the lectures which he would deliver, his endeavor would be to draw particular attention to the intimate connection which existed between the different branches of science. The simple laws of motion stood at the beginning of the study, and when they were thoroughly understood, they would be able to understand the conservation of energy and the connection which existed between the different branches of science in relation to the methods by which discoveries had been made. From the time of the Greek philosophers, until 200 or 300 years ago, hardly any progress was made, but that which had been made since was very great, and it seemed likely to go on, because people had learned to rely upon facts rather than upon arguments and theories. In conclusion he said that his object was not to give any description of the latest modern discoveries, but rather to accept the march of science as a whole from the earliest principle up to the present time, keeping in view the close connection between the different branches, and by means of illustration to show the method by which it had moved forward.—*London Iron and Steel Trades Journal*.

MECHANICAL PROGRESS

A Point About Steel.

The causes from which trouble may come with steel are innumerable.

The rapid multiplication of small, portable forges is doing much to increase a certain kind of trouble with it, and, in fact, this particular cause of trouble with steel has assumed proportions of considerable importance, and by pointing out, as we propose to do, some of the limitations of these small forges, we hope to be able to render a service to steel-users and steel-makers, and to the makers of the forges as well.

Mechanics understand perfectly well that a hammer must bear some proportion to the size and weight of the piece of steel that is to be forged with it; but it is not so generally understood that this is also true of the fire and forge in which the steel is heated. Of course, we do not mean to say that a different size of forge should be used for every variation in weight of work; but we do mean to call attention to the fact that a furnace suitable for heating for a steam hammer is unfitted for tempering small drills and taps, and that a small portable forge is utterly unfitted for heating a steel die weighing 20 pounds or more.

Such forges have their uses, to which they are well adapted, but when a large piece of steel, such as a drop or trimming die, is to be heated for hardening, the conditions necessary to the success of the operation cannot be secured with such a forge. It is well settled that when such a piece of work is to be heated, there must be a good body of clear fire, and that a considerable bed of the fuel must be below the work, between it and the tuyere openings. Then the character and distribution of the blast must be such as to keep this body of fuel at a nearly even temperature, and while its volume may be large, it must not be fierce and sharp, but mild and gentle.

Just the opposite of these conditions are present with a small portable forge. No large body of fuel can be heated evenly upon it; the blast coming from a few small tuyere openings, closely grouped together, must be sharp in order to get sufficient heat, and the result is an effect similar to that of a blowpipe, with intense surface and local heating, instead of the evenly distributed low heat absolutely essential to success in hardening such work. Then, too often, when the work cracks to pieces in quenching, the steel-maker is blamed.

Of course, there is little of this particular kind of trouble in the large shops, for in them regular forges are always found, and it is to the owners of the small shops, particularly where "rooms with power" are hired for manufacturing purposes, that this is addressed, in the hope that it may show some one a cause of trouble with steel, not previously suspected.

Such small forges as we refer to are excellent for the class of work for which they are intended, and small tools can be hardened with them as well as with any other forge, especially if charcoal is the fuel used; but it should be recognized that they, like most other things, have their limitations. It should be remembered, too, that pure, soft water is a good, if not the best quenching liquid, and that water in which more or less washing of hands with soap has been done is not pure water. The water and the tub containing it should be clean.—*American Machinist*.

A NOVEL STEAM ENGINE.—One of the most recent plans of engine construction assumes to overcome some of the peculiar difficulties hitherto experienced, by a duplication of all the moving parts. The engine is an upright, and has one cylinder fitted with two pistons, these approaching each other to within a very small clearance in the middle of the cylinder. There are three cranks, the middle one directly connected to the lower piston, and the two outer cranks set at 180° from the middle one, so that

when the center crank is descending, the outer cranks are pulling upward; the outer cranks are connected by rods to a trunnion ring sliding over the lower cylinder, this ring being moved up and down by means of two rods extending to a cross head at the top of the engine operated by the piston rod of the upper piston. The engine is single-acting, and steam being admitted between the pistons, they are forced apart, the upper one exerting power on its upward, and the lower one simultaneously on its downward stroke, the return stroke being performed by the momentum of the fly-wheel. The steam is admitted by a double piston valve, the outer valve acting as a fixed cut-off valve, the engine being governed by a throttling governor and running at 100 revolutions per minute. The arrangement of two pistons moving simultaneously in opposite directions has the advantage of completely relieving the main bearings of any pressure. The pistons are made extra long to reduce wear, which in the case of the lower piston is a point of especial importance, since the cylinder itself acts as a guide. Springs are introduced into the various bearings.—*Eng.*

Modern Boiler Shops.

In these days of enormous pressures, special tools are required to handle the very heavy plates of which boilers are now made. An English boiler shop is thus described in *Engineering*:

In the boiler shop the plates are taken in in the center bay, and, having been marked off, are planed on the edges, the edge planers taking 30 feet in length and 8 feet across. The plates are taken up the center bay, the work being done on them while in the straight. At the top of the bay there are large vertical rolls, recently erected, which will take plates 12 feet wide and bend 1½-inch steel plates cold. The end plates are drilled, manholes out, etc., in the center bay. When the shell plates are bent to the required radius, they are taken to the next bay and bolted together. They are then drilled in position by the ordinary drilling machines designed for this purpose. The end plates are flanged by a hydraulic press, furnace holes having been cut, etc., and rivet holes drilled in position. The back plates, combustion chambers, etc., are then put in, and the whole riveted up. For the latter purpose there are hydraulic riveters, one shell riveter of 150 tons and having a gap of 12 feet 3 inches. The work, as stated, is well arranged so as to prevent, as far as possible, the same ground being twice covered and there are hydraulic cranes well arranged for handling the parts.

Among other tools may be noticed another hydraulic riveter with power of 90 tons and a gap to take a ten-inch plate; an oval hole-cutting machine for manholes, with variable eccentricity up to seven inches; a boiler back-stay drilling machine, with two standards, and having a vertical range of 12 feet and a bed 30 feet long. The hydraulic flanger referred to has a power of 150 tons, and is capable of flanging steel plates 19 16 inch thick. The shell drilling machine has a range of ten feet vertically and an angle of drill up to 25 degrees.

ARMOR PLATE.—It has been stated that armor plate composed of steel containing an alloy of nickel has shown a greater power of resistance than plates of pure steel. In a more recent contest, held at Annapolis, nickel steel plates which had been subjected to a process of superficial carbonization were shown to be greatly superior to the ordinary nickel steel. Four kinds of plate were tested—pure steel, nickel steel; pure steel subjected to the carbonization process, and nickel steel likewise treated. The pure steel plate was smashed to pieces; the treated steel plate stood the test better, but the treated nickel plate was practically unharmed, the projectiles being broken. It is estimated that this discovery will reduce the weight of armor by about 25 per cent; that is, armor of 25 per cent less thickness will afford the same degree of protection as before. If the degree of protection formerly afforded is allowed to remain as the standard, coal capacity and other accommodations may be greatly increased. The carbonization process was the invention of H. A. Harvey of Newark, N. J.—*Eng.*

A WOODMAN'S TEST FOR AXES.—A hint which may be serviceable to ax-manufacturers as well as buyers was given by an experienced Australian bushman to a new chum. "It may be useful to you when you go into a store to buy an ax. Take out your pocket-knife, open it, and hold it as if you were going to sharpen a pencil, but with the back instead of the edge toward you. Then run the back of the knife gently over the edge of the ax. If the edge turns ever so little, so that you can just feel it, the ax is all right. If it won't turn, it is too hard." Trying an English-made ax lying at hand, he said, "That's no good." The edge would not turn.

WIRE NAILS FROM STEEL PLATE.—It has always been considered impossible to cut wire nails from any material except wire, but it is reported that an ingenious arrangement has been introduced into a mill in Pittsburgh which enables wire nails to be made from steel plate. This invention may be attached to the ordinary cut-nail machine, and is said to be capable of producing perfectly formed nails in greater quantity than is possible by the present wire nail.—*Philadelphia Record*.

GOOD HEALTH.

Swallowing Pins, Twigs, Etc.

Several cases of accidental swallowing of things other than food have come to notice since the lamentable death of Rev. Dr. Bothwell of New York, who recently died from swallowing a cork, which lodged in his windpipe. The first is that of a locomotive engineer, who, several years ago swallowed a piece of wood. He was subsequently treated for consumption, on account of violent coughing, but without the other usual accompaniments of such a disease. One day the man had an unusually severe fit of coughing, accompanied by a violent pain in the trachea, in which something seemed to have lodged. With an supreme effort, he ejected it, and it was found to be a piece of wood about an inch long and of the thickness of a lead-pencil. It was thickly coated with mucus and as black as coal. A slight hemorrhage followed, after which the patient felt great relief. He then recollected that one day while running his train he stopped at a depot, beside which there grew an apple tree. He carelessly broke off a small twig and put a piece in his month. The train again got under headway, and, while running at full speed, he saw a bull on the track a few yards ahead of the engine. He quickly applied the airbrake and reversed his lever, in order to render the inevitable shock as light as possible. In the sudden surprise, coupled with the strain of throwing back the lever, he made a convulsive inspiration, and unknowingly inhaled the piece of twig, but, in the excitement, forgot all about the swallowing until it was ejected as above. He completely recovered under the care of Dr. Downs of Brooklyn, New York.

Another case is one which also closely parallels that of Dr. Bothwell. It is related by the *Baltimore Democrat*, of a late date, that Annie Glaesner, aged six years, is dying from the effects of a pin sticking in her throat, which two weeks ago she drew in with a breath in the same manner in which the Rev. Dr. Bothwell inhaled the cork. The accident occurred in school. The child was suddenly seized with a violent fit of gagging. After the paroxysm, she informed the teacher that she had been holding the pin between her teeth, when, in an effort to yawn, she drew it down her throat. She was taken to a hospital, but as yet the doctors have been unable to locate the pin. At times the child suffers terribly, and then she will not feel it again for several hours. The throat is swelling, and it is feared that blood-poisoning has set in.

We have not yet seen any report of the result; but such accidents should be a warning against the too common practice of unnecessarily placing such things in the month. There is always great danger in doing so.

DON'T GET SEASICK.—Lemons, oranges, champagne—all these are recommended, says the *Ladies' Home Journal*, but the best recommendation, the most practical and common sense, is to let the seasickness have its way, and then you are over with it. You can modify any possible attack by a little care as to diet a day or two before sailing, by avoiding greasy and rich foods, and this is wise. But don't go on board with the settled idea that you are going to be sick. Dismiss the thought. Keep on your feet the first day out. Walk up and down the deck continuously. By this method you get accustomed to the motion of the ship, tire yourself out, and, if you are any sort of a sleeper, you will sleep soundly the first night. Then the worst is over. But if not, and you do get sick, just accept it philosophically. Of course, you will feel miserable. But let the spell run its course, and it is done; and you are better for it, and certainly wiser than to try and cure it by a mixture of things, which only give the stomach a reason for a continuance of proceedings. One of the leading medical authorities in the world says that 15 grains of sulphate of quinine, administered two hours or four hours at the most before embarking, will completely free even sensitive subjects from the horrors of seasickness.

HOW TO AVOID A MAD DOG.—A good thing to know is that a mad dog never turns aside from the course he is running to bite anybody. So if one is right in the path of a rabid animal he can get out of all danger by jumping to one side and out of the path of the dog. But if it is absolutely impossible to get out of the way, the man or woman should stand perfectly still and face the dog. He will turn aside then himself and run in a different direction, while if the person in front of him sreams and runs away, as nine out of ten will do, the dog will overtake and bite the victim. Of course it requires courage to stand still and face a rabid dog, terrible as this animal always looks, but the result shows that the real danger lies in taking flight.—*Pittsburg Dispatch*.

DANGER IN FRENCH CANNED GOODS.—Extensive investigation by the Massachusetts Board of health into French canned vegetables has resulted in the order prohibiting their sale in Boston. In every sample tested, it was found that metallic poison existed in the form of copper, and 27 out of 37 samples showed adulteration.

THE GRIPPE in London is attacking the horses.

USEFUL INFORMATION.

A Comparison of Young Mechanics To-Day and those of Former Times.

Few of the young mechanics of the present time appreciate the many advantages by which they are surrounded, making comparison with the situation as it was a generation ago. The young mechanic who thinks it harder to take the front rank at the present time than it was for his father to achieve excellence in the same pursuit in his time, should be reminded of the many advantages which he enjoys that his father knew nothing about. In his father's time there were no technical schools. Text books on mechanical subjects were almost unknown. No mechanical papers were published. Mechanical dictionaries were unheard of things; large factories never dreamed of maintaining circulating libraries for the benefit of the mechanics employed. Popular lectures on mechanical topics were not thought of. Free night schools for instruction in drawing had never been attempted.

And these are only a few of the many advantages that surround the young mechanic of the present time, the intelligent improvement of which will lead him on to success. It is with him, however, as with children who frequently have too many toys; they soon learn to think so little of them as to fail to appreciate their actual value. So many advantages are crowded upon the young man of the present day as to leave him little opportunity of considering their value, or of learning to appreciate their worth. It is for this reason, with others, that so few of the mechanics who are surrounded with exceptional advantages reach eminence in their trades.

A qualification that the mechanics of 40 or 50 years ago possessed, and which is sadly lacking in the youth of the present day, is self-reliance and enterprise. Our boys have so many helps, and things are so generally prepared for them, both in the public schools and in other departments of our educational system, that they acquire the habit of abject dependence. They fail to acquire the habit of asserting themselves and investigating upon their own account. To this difference is to be ascribed, in many cases, the failure of the mechanics of the present day to profit by the unusual opportunities by which they are surrounded.—*Blacksmith and Wheelwright*.

REGULARITY OF HABIT.—One of the most difficult of all minor habits to acquire, says *Iron*, is that of regularity. It ranks with that of order. The natural inclination of most persons is to defer work to be done until the last possible moment, or to put it off to another time, where this can possibly be done. Yet habits of regularity contribute largely to the ease and comfort of life. A person can multiply his efficiency by it. We know persons who have a multitude of duties, and who perform a vast deal of work daily, who set apart certain hours for given duties, and are there at the moment, and attend rigidly to what is in hand. This being done, other engagements are met, each in order, and a vast deal is accomplished, not by strained exertion, but by regularity. The mind can be so trained to this that at certain hours in the day it will turn to a particular line of duty, and at other hours to other and different labors. The very diversity is retained, when attended to in regular order. But let these run together, and the duties be mixed, and what before was easy is now annoying and oppressive, and the exact difference between persons is at this point. There are those who confuse and rush, and attempt to do several things at once, and accomplish little, while others will quietly proceed from one duty to another, and easily accomplish a vast amount of work. The difference is not in the capacity of two men, but in the regular methods of the one, as compared with the irregular and confused habits of the other.

A HINT FOR CIGARETTE SMOKERS.—We clip the following from the *Poughkeepsie Eagle*, and give it for what it may be worth. We trust, however, it will not result in any encouragement of the pernicious habit of cigarette smoking, as, even if it be true, it accomplishes nothing in the way of removing the unhealthy effects of such practice: A gentleman whose lungs are not strong enough for him to enjoy the fumes of tobacco after a dinner party, took with him to a friend's home a little lamp which he set on a table when the cigars were lighted. Over the flames of this little lamp was a ring of platinum, which became red-hot in a very few seconds, and which consumed the smoke of a dozen cigars as fast as it was made, so that the atmosphere of the room was as clear as it would have been had there been no smoking going on at all.

TEN CENT PIECES.—The superintendent of the Philadelphia Mint says that ten cent pieces, instead of weighing as much as a silver dollar, as formerly, only weigh about nineteenth as much.

THE PATENT OFFICE at Washington has a printed circular which it sends to inventors of machines for "perpetual motion," setting out the fact that the thing is an impossibility.

VOLAPUK.—Upward of 300 business houses throughout the world conduct a portion of their correspondence in Volapuk.

STEAM BOILER NOTES.

USING STEAM EXPANSIVELY.—One volume of water heated until it is converted into steam at atmospheric pressure becomes increased to 1011 volumes. A very ready way of remembering this is, to put it that one cubic inch of water converted into steam at atmospheric pressure becomes one cubic foot of steam. This is so nearly true that the figures may be used for all practical purposes as follows: $12 \times 12 = 144 \times 12 = 1728$; while the real product of converting one cubic inch of water into steam is 1711—only 17 inches in excess of the figures first given. The most economical way to use steam is to use it expansively. Where this is done, the cylinder is only partly filled with steam, the remainder of the stroke being carried out by that steam being allowed to expand. When hot steam is in contact with the water it has been generated from, it is known as *saturated steam*. There is no law governing the relationship of its pressure to its volume. The thing is empiric, so to speak, and has to be determined by experiment for every temperature. The results of such experiments are to be found in published tables, but it is not as with steam that has been removed from the surface of the water that generated it, but is kept as hot as the latter. Then it is known as *non saturated steam*; then it acts as a perfect gas. It is governed by a definite law known as Boyle's or Mariott's law. Boyle, by the way, was an Englishman and Mariott was a Frenchman. They both experimented, and found the law out at about the same time, so they both get the credit of it. That law is this: The volume of gases—air, coal, gas, natural gas, hydrogen, steam in the *non saturated* condition, etc.—varies inversely as the pressure—that is, if you double the pressure you have the volume, and *vice versa*.

BRIGHT THOUGHTS FOR STEAM ENGINEERS.—No one furnace is best for all fuels, and rarely for more than one. It pays to have men of brains as well as brawn and muscle, even for firing fuel and watching water. It is to the furnace we must look largely for the ability to meet the sudden fluctuations in demand for steam. It is well to understand that there is no such thing as "burning smoke," but furnaces can be made to produce a minimum quantity. Set down all claims to the evaporation of over 12 pounds water per pound of combustible (unless it be oil, gas or hydrogen), under any conditions, as made ignorantly or with an intention to deceive. When we consider that, in constant running, a boiler, to speak figuratively, eats its head off every three or four months, it is plain that a reasonable additional cost for an economical boiler is a first-rate business investment. In other words, a boiler which would save ten per cent of the coal would pay 30 to 40 per cent on its cost annually, and would be cheap at a round price as against another as a gift.—*Modern Light and Heat*.

A NOVEL FORM OF CONDENSER has been successfully introduced in Germany and other parts of the Continent. The exhaust steam from the engine passes through a series of brass pipes immersed in water, to which it gives up its heat, and between each section of tubes a number of galvanized disks are caused to rotate. These disks are cooled by a current of air supplied by a fan, and pass down into the water, cooling it by abstracting the heat given out by the exhaust steam, and carrying it up where it is driven off by the air current; the disks serve also to agitate the water, and in this way aid in abstracting the heat from the steam. With this arrangement, and with 85 per cent vacuum, the temperature of the cooling water shows about 130° F., and a consumption of water for condensing is assumed to be less than a pound for each pound of steam condensed. For an engine 40 or 50 inches, 70 revolutions per minute and 90 pounds pressure, there is about 1150 square feet of condensing surface. Another condenser of 1600 feet condensing surface is used for three engines, 32 inches by 48, 27 by 40, and 30 by 40, respectively.

DANGER IN THE FLUES.—After prolonged official investigation, the most extensive and complete destruction of steam boilers on record has been attributed to the sudden ignition of coal gas, mixed with air, that had accumulated in the flues. The explosion occurred July 25, 1887, in Upper Silesia, Germany. Twenty-two boilers, each with more than 1000 square feet of heating surface, were instantly blown to pieces, holdings covering half an acre were destroyed, and three men were killed.

AN ENGLISH INVENTOR, desiring better lubrication of indicator pistons has an internal reservoir formed in the body of the piston, so that the steam pressure, acting on the surface of the lubricant, forces it through small outlets into a groove on the outer surface of the piston. The piston is thus continuously lubricated and the oil under pressure in the groove forms a packing. One piston full of oil will last while taking 24 diagrams.

COMPETITION.—The close competition in the machinery interests is what puts on the market the best machines human ingenuity can devise. If it were not for this competition, there would be little inducement for the machine-builder to spend money in making improvements.

SHOP NOTES.

The Accuracy of Handwork.

A writer in a late number of the *American Machinist*, says: "One of the principles upon which the accuracy of handwork much depends, is that having made a test of the work, the cutting tool held in the hand, can be applied to reduce only the high places, without touching the low ones. This can go on indefinitely, so that the work finally becomes as accurate as the test is capable of detecting."

The test of finding the high places by rubbing one piece upon another is one of the most delicate in the whole range of machine-shop practice. In order to form an idea of the delicacy of this test, let us rub a cylindrical piece, one inch in diameter, upon a surface plate. Now, if in the cylindrical piece we rub off a flat place six one-thousandths of an inch wide, which is the width of lines on a common scale, we shall reduce the piece only one-hundredth of an inch. Hence, with a perfect surface plate, this test for the straightness of a cylinder is far more delicate than any other that I have spoken of.

The perfection of surface plates is also an example of this test. We have not yet made a machine that will make plates as nearly perfect as they can be made by hand."

[The finishing of the object glass of a telescope of the magnitude of that in the Lick telescope at Mt. Hamilton is, perhaps, the most pronounced example of perfection in hand finishing which can be cited. There are, probably, but two or three men living who can do such work as perfectly as in the case mentioned. No machinery could possibly be devised that could make any close approximation to it.—*EDS. PRESS*.]

"In every test," continues the writer alluded to, "we may be met by difficulty from the elasticity or springing of the pieces. To illustrate the elasticity of hardened steel, let us have it in the forms of a one inch plug and a closely-fitting ring. Now, take another plug a ten-thousandth of an inch larger, and we shall find that it can be put into the ring, when well oiled, and that it may be moved easily, as if not fitted tight."

"To file two templates so as to exclude light, requires a touch as delicate and as true as that of a musician or of a painter. A minute's watching an expert in such work, will convince any one that he must be eminent in his specialty."

And now comes the thought that presents itself through a variety of phases—Can a man be pre-eminent in any specialty without paying too dear a price for his eminence? Is the fact of this eminence a clog to his being fairly proficient, or, perhaps, companionable in general lines of thought? If this workman carries thoughts of his work home with him in the evening, and has them on Sundays, and is never happy unless he is working to a thousandth or the ten-thousandth of an inch, it seems to us that he is not getting quite all out of life that he ought to get. I should like to be acquainted with him, to know what books he reads, and how he thinks. I hope to know more of him some time.

AWKWARD MECHANICS.—Mechanics are often addicted to what can only be called awkwardness. In getting at a new or strange piece of work, some men make so much fuss, and appear to such poor advantage, that surprise is expressed that such an incompetent man should be employed. Most of this awkwardness, or "fumbling," could well be avoided by the man if he would only see himself as others see him. His attention is too much taken up by some detail of the matter, and he does not comprehend the whole amount of his work. A thorough mechanic gives a thing a thorough thinking over before he proceeds to execute any work. If the awkward mechanic would learn to think more, he would appear to much greater advantage, and would be worth more money to his employer.

BALL BEARINGS FOR ENGINE SHAFTS.—Roller or ball bearings for engine shafts have not met with success enough to warrant adoption generally. A popular make of roller bearing, recommended and used on our wheels, was tried on the air engine at the late Mechanics' Fair in this city, but worked so unsatisfactorily it was removed. While it seems to work well enough for a continuous rotary motion it did not stand the thrust of the connecting rod on the centres. This was where the difficulty came. There is a chance here for inventors.—*Boston Journal of Com.*

GERMAN ENGINEERS are said to be adopting new lining for bearings, composed of compressed vegetable parchment. When lubricated with an emulsion of mineral oil and water the parchment becomes impregnated with the oil and will last for a considerable time.

SHOP HINTS.—Never lay tools or other things on belts that are standing still, for they may be forgotten and cause a break-down when the machinery is started. If babbit is used for the boxes use only a good material; do not adopt the common mixture of tin, antimony and lead.

Passing Events.

The decision of the Supreme Court settling as unconstitutional the purchase of mining shares on a margin is quite a blow to the mining-stock business on Pine street, and the brokers are now conferring with counsel to get a clear understanding of the meaning of the decision. If as broad as it appears, it will interfere greatly with mining-stock sales; and if of general application, must affect speculative sales in other branches of business as well.

Times are bad for miners at Batte and Anaconda, Montana, owing to the shutting down of the mines and smelters at Anaconda, which threw some 3000 men out of work. There are too many miners also in some of the new Idaho camps. It is just as well for miners elsewhere to stay away from the Northwest for the present.

The acquittal of Mr. Kerr, proprietor of the Occidental foundry, for killing Edward Coogan in defending himself, and an employe from a gang of strikers, was to be expected, and is a rebuke to those men of the unions who tried to carry their points by riotous acts.

Mining Stocks on Margins.

The Supreme Court has rendered a decision to the effect that selling mining stock on margin is not lawful, which has created quite a stir among the brokers and the stock exchanges. The particular section of the Constitution under which the Court ruled, reads: "All contracts for the sale of the capital stock of a corporation or association on margin or to be delivered at a future day shall be void, and any money paid on such contracts may be recovered."

The appeal to the Supreme Court, which resulted in this decision, was made in the case of Geo. B. Root et al. vs. William F. Cashman. Cashman dealt in mining stocks on margins with a broker named Hooker. Hooker's business went into the hands of an assignee, and Cashman was sued for \$2,347, the amount of indebtedness which appeared against his name on Hooker's books. In the lower court, the plaintiff got judgment. Cashman appealed, holding that the debt was illegal, and the contract to pay void under the Constitution.

The lower court held that the stock was purchased by Hooker as agent of and belonged to Cashman, and that Hooker never sold stock to or bought from Cashman. No part of the indebtedness, therefore, arose from the sale of stock on margin or otherwise. The broker did the buying and selling of the stock, and the customer took the gains or paid all the losses arising from the transactions.

The Court calls attention to the fact that it was to put a stop to just such transactions that the quoted clause was placed in the State Constitution, and such a prohibition, says the Court, is of little worth if it can be evaded by so simple a device. "A party wishing to purchase on margins has but to interpose his broker, who is to carry the stock instead of the original owner. This would not diminish the evil. In fact it is the very form of the evil mainly intended to be prohibited."

In the accomplishment of the unlawful purpose, the Court holds, the broker put himself in the position of vendor and carried the stock as the vendor might have done, and the end was thus reached. The end attained, and not the form of the transaction, must determine the question. It is ordered that the judgment be reversed, and a new trial be given. In so deciding that in buying and holding stock for a customer the broker takes the position of a vendor, the Supreme Court makes every broker in Pine Street amenable to the law of the Constitution, and suits innumerable will result.

CRUISER No. 13 is to be built at Bath, Me., and not in San Francisco, as was hoped for. The bids were as follows: Cramp & Sons, Philadelphia, \$2,745,000; Union Iron Works, San Francisco, \$2,793,000; Bath Iron Works, Bath, Me., \$2,690,000. The result was a complete surprise to nearly every one, as the Bath Iron Works is comparatively a new competitor in the construction of steel vessels.

E. N. RIOTTE, of New York, died in North Carolina a few weeks since, where he was building a gold mill. Mr. Riotte was for many years a resident of this city, where he was engaged in business as a metallurgist and assayer with Mr. Luckhardt and with Mr. Kustel. He was known all over the coast as a mining expert, having visited most of the prominent districts on professional business.

A PARTIAL eclipse of the sun occurs on hour and twenty minutes after sunrise on Saturday morning. In San Francisco the total obscuration will be about one-third and the eclipse will last one hour and forty minutes. The eclipse begins here at 6h., 10m., 42 sec. A. M. and ends 7h., 48m., 28 sec.

MRS. LELAND STANFORD'S monument to Father Junipero Serra, the founder of the California Missions, was unveiled at Monterey, on Wednesday last, with appropriate ceremonies.

MR. W. E. WEST, manager of the sampling works of W. J. Chamberlain & Co., of Austin, Nev., is arranging for the establishment of sampling works at Cerin.

CHARLES STEPHENS, Secretary of the Trustees of the Academy of Sciences, died suddenly of heart disease while at work in his office, on Wednesday.

The Late J. M. Buffington.

J. M. Buffington, who was one of the best-known mining secretaries on this coast, died at his home in Oakland on Saturday, in his seventy-third year. Mr. Buffington came from his birth-place, Somerset, Mass., to California, June, 1849, and, like all the pioneers, immediately engaged in mining. He was fortunate in his work, and in about a year was enabled to start in business in San Francisco, where he became interested in a ship-cracker bakery, which proved successful. After some years in this business, he again engaged in mining, and was interested as a stockholder in many of the more prominent mining companies in this State and Nevada.

During his life, he has had charge of the financial affairs, as secretary of over a hundred mines. He continued to act as secretary for a number of prominent mining companies up to the time of his death, although he had accumulated a handsome fortune.

His residence on Oak street is one of the finest in Oakland, and one in which he took great pride. Mr. Buffington was active in church affairs and established the first Sunday-school in Stockton. He was acting President of the Young Men's Christian Association of Oakland for six years, and for the past few years has been its honorary President. The deceased was a prominent member of the Scottish Rite of Masonry and was a thirty-third degree member.

Mr. Buffington has been quite feeble for many months and his death was not unexpected. He has always been a man of affairs, active and industrious. He enjoyed the confidence of the mining magnates of the coast and was an officer of some of the most noted Oomstock mines during their palmiest days. He was a man of exceptional personal integrity, respected by all with whom he had dealings. While quiet and unassuming in his ways, there were strong points in his character which made him many warm friends. Mr. Buffington leaves a handsome fortune to his heirs. There was a large assemblage at the funeral, the Rev. Drs. Dille and Benton conducting the ceremonies. The Y. M. C. A. quartet rendered selections. The pallbearers were: E. W. Playter, N. W. Spaulding, W. E. Miller, Hiram Tubbs, E. W. Marston, George E. Whitney, E. B. Deane and J. L. N. Shepard.

MEXICAN LEAD ORES.—The Secretary of the Treasury has concluded the consideration of question of the examination and assay at El Paso of ores containing lead, and which are destined for other ports of entry or delivery at which there are smelting works. The Collector at El Paso is authorized to forward such ores under warehouse and transportation bonds, the examination, weighing and assay to be waived at that port, and to be made at the port of destination. Bonds will be taken in the usual form, the penalty being fixed at double the estimated duty. In estimating the duties, the entire importation will be regarded as lead ore. The merchandise must be forwarded to destination in sealed cars, and by duly bonded routes.

At Red Mountain Camp, Colorado, a meeting of American miners has been held to protest against the action of the management of one or two large mines, which, it is alleged, give employment to miners recently from the old country, in preference to residents and citizens who have blazed the trails and opened up the country.

MINERS ARE WARNED to stay away from Idaho. There are said to be ten applicants for every vacancy at the De Lamar mines, and the Seven Devils country, although landed by the Idaho papers last year, as one of the wonderful mining camps of the country, is now admitted to be a place that poor people should keep away from.

PRENTICE MULFORD, who has written many stories of mining life and early days of California, was found dead in his canoe on Sheephead bay, last Saturday.

THE *Daily Alta California*, after having been published in San Francisco for 42 years, has gone out of existence. It has been unprofitable for some years.

THE personal property tax roll of San Francisco shows an increase of \$1,245,934 over last year.

Electric Percussion Drills.

(Continued from page 353.)

to feed about 20 inches, and is designed for a hand feed. Its weight, with tripod complete, is about 400 lbs., and its length over all is 38 inches.

There is no valve arrangement, the shifting of the force being independent of any movement of the plunger, and is effected periodically at the generator. This feature makes it possible to shorten the stroke almost indefinitely. The plunger is automatically cushioned by the magnetic action of the coils, and vibrates in space without striking anything at either end of the stroke.

Every part of the machine is easily renewed, and a duplicate can be inserted in a few moments. The electrical connections with the coils are so simple, and of so evident a nature that no experience is required to make them, and they cannot be made wrong.

In introducing the wires through a mine, a simple expedient insures the certainty of unskilled persons always making right connections of the wires.

Blasting is easily effected by touching the wires from the blast to the connection on the cable, and 50 or more blasts may be simultaneously exploded, if desired. Owing to the intermittent character of the current, it cannot hold an arc, and there is thus no danger of fire.

The short, rapid stroke of the machine is very effective in cutting hard rock, and very easy on the cutting tool. The coils cannot burn out, and are impervious to moisture, being hermetically sealed. They are easily removed.

Another cut on page 353 shows the electric hoisting apparatus for mines manufactured by the same company that makes the electric drill. The construction of the hoist is readily understood from the engraving.

The Astronomical Society.

The next regular meeting of the Astronomical Society of the Pacific will be held in the library of the Lick Observatory, Mt. Hamilton, on Saturday, June 13, shortly after the arrival of the members. To attend the meeting, members must take the 7:30 A. M. train (broadgauge) from foot of Market street (via Niles), arriving at San Jose shortly before 10 o'clock, on Saturday morning. They will be met at the broadgauge station by the stages of the Mt. Hamilton Stage Co. The start from San Jose will be made very promptly at 10 o'clock, in order to arrive at Smith Creek about half-past one. Here dinner can be had, and by starting promptly, the summit can be reached by about 4 o'clock. A meeting of the Board of Directors will be held in the library immediately on arrival, and as soon thereafter as may be, the meeting of the society will be called to order.

At 7 P. M. the domes of the 12 inch and 36 inch Equatorials are opened, and all visitors take their turns in looking at the most interesting celestial objects which are in a convenient situation.

About 10 P. M. the visitors leave, and the members of the Society will then have a further opportunity of seeing other heavenly bodies. The stages will leave the summit about 11:30 P. M. for Smith Creek hotel. The stages returning to San Jose leave Smith Creek as the members desire, in time to connect with the various trains to San Francisco.

At the meeting on Saturday, the following papers will be presented:

"The Solar Eclipse of June 6, 1891," by Orrin E. Harmon of Chehalis, Washington.

"The Thermometric Chronometer of the Lick Observatory," by A. C. Leuschner of Berkeley.

Review of Miss Clarke's "The System of the Stars," by George E. Hale of Chicago.

Review of Dr. Dreyer's "Life of Tycho Brahe," by Torvald Kohl of Denmark.

"The Period of the Rotation of the Sun Near the Poles, as Derived from the Coronas of 1878 and 1889," Prof. F. H. Bigelow of Washington, D. C.

"The Visibility of Interference Fringes in the Focus of a Telescope," by Prof. Michelson of Worcester, Mass.

"Observations of the Transit of Mercury, May 9, 1891," by Messrs. Burkhalter, Moses and Pierson (Oakland and San Francisco) by Messrs. Holden, Burnham, Schaeberle, Keeler and Barnard (Mt. Hamilton), by Prof. Soule (Berkeley), Prof. George (San Jose), Gen. Irish (Reno, Nev.), Mr. Parmley (Ogden, Utah) and others.

The new powder works at Clipper Gap are now running night and day.

Methods for Moving Engines.

There are different methods that can be used for taking engines off the center or dead points. In the last annual report of the Secretary for Mines of Victoria are some statements on this subject which are of general interest and application. The plan in common use to turn marine engines when steam is down could be adopted, viz., a worm-wheel is keyed on the crank-shaft; in this works a worm-pinion, which is also keyed on another short shaft, the top bearing of which is a sliding one, and by this the pinion can be shifted in or out of gear, and turned by means of a hand-wheel on the top.

Another method is to fix a small auxiliary cylinder vertically under the crank-shaft (if the engine is a horizontal one). This cylinder would have a piston and rod, cylinder ends, and a connecting-rod to the crank-pin of the large engine, also slide-valve and rod, and a large cock on each end of the cylinder. These cocks and the valve could easily be worked by one handle from where the engine-driver stands.

METHODS FOR MOVING ENGINES WHEN ON A CENTER.

The opening of the valve would shut the cocks, and vice versa. The power used could be either steam, compressed air, or water, and would be under perfect control.

When a large engine is centered, the engine-driver can open the port by the slide-valve and admit the power used on either the top or the bottom of the piston, to suit the direction in which he required the crank to move; and when it was off the center the ports would

then be closed, and the auxiliary cylinder would not be required again except the crank again stopped on the center.

The disadvantage attending this plan is, the small piston would require to be propelled up and down in the cylinder by the crank; but, the cocks being open, there would not be much friction.

Instead of turning off the power, the small cylinder might be kept always at work, and so

assist the large engine; but in this case additional appliances to work the small slide-valve would require to be added.

A method of moving an engine when the crank is on the center is shown in Diagram No. 1, printed herewith.

The cylinder *A* is fixed vertically under the center of the crank-shaft, and from the cross-head *B* the connecting-rod *C* is fixed to the crank-pin, which is made a sufficient length that will allow a journal outside the journal of the main connecting-rod.

The slide-valve is worked by the handle *D*, and when this handle is in the center of the quadrant, as shown, both ports are covered; by moving the handle *D*, the power is admitted either on the top or bottom side of the piston, as required. The handle *D* also works the two large cocks *E E*, which are so arranged that opening the ports shuts the cocks, and closing the ports opens them. By this arrangement, when the power is shut off, the open cocks

wedge piece *G* could be used at the back of the top brass to keep the worm-pinion in gear; and when out of gear, the wedge could be shifted to the front of the brass.

The Academy of Sciences.

At the last meeting of the California Academy of Sciences, Melville Atwood presented a paper on opals, with specimens in the matrix from Washington, Mexico, Australia and Hungary. A brief memoir of the life and character of the late Prof. John Le Conte of the State University was read by Theodore H. Hittell and

was ordered spread upon the minutes of the society.

The address of the evening was made by Lieutenant Finley, in charge of the Signal Service, whose subject was "The Hot North Winds." He said that the general idea of these hot desiccating winds that prevail in California at certain seasons, and which do so much damage at times to orchards, farms and gardens, is that they are of local origin, but he was prepared to show this idea to be erroneous. He explained by means of a series of charts that the meteorological changes in climate noticed in the State proceed from conditions that are created over an immense area of territory that begins among the Aleutian Islands and that ends only at Mexico.

In order to have accurate and timely warnings of the approach of these hot seasons, stations should be established in the Aleutian Islands, at Sherlock, British Columbia, and be connected by telegraph with San Francisco. All this will require money, however, which the Government does not see fit to provide. Reports are made regularly in British America, but they are not received here for six months, so they are of little practical value. The speaker then proceeded to show that the hot winds are produced by certain climatic changes in this part of the State proceeding changes in the cyclonic centers of storm areas, which are clearly marked and can be traced for days before their effects are noted at the various stations.

When certain barometric conditions occur the interior of British Columbia, Eastern Oregon, Washington and the interior valleys of California are shut off from the trade winds for days and weeks. When the entire extent of lava beds, alkali plains and deserts receive the full force of the sun's rays, then these hot, desiccating winds sweep over the land for three

prevent friction in the cylinder.

Another method (see Diagram No. 2) which is used to move marine engines when steam is down could be adopted. The crank-shaft *A* has the worm-wheel *B* keyed on it, and the worm-pinion *C* being turned by the hand-wheel *D* causes the crank-shaft to revolve. When required to be taken out of gear, the step brass swivels in the bottom bracket *E*, and the top brass slides back in the top bracket *F*. *A*

days and inflict serious injury to every kind of vegetation. The moment the conditions change a sudden fall in temperature takes place, which is frequently remarkable for its variation.

Lieutenant Finley said that the only remedy for this wind is to plant trees or grass upon the alkali plains and to cultivate the lava beds. If farmers in the interior valleys would plant rows of quick-growing trees for wind-breakers, as was done in Nebraska a few years ago, there will be something to protect their crops.

VALUABLE BOOKS FOR SHEET METAL WORKERS.

The Sheet Metal Worker's Instructor for Zinc, Sheet Iron, Copper and Tin Plate Workers, and others; Geometrical Problems; Practical and Simple Rules for describing the various Patterns. By Reuben H. Wain, Tin Plate Worker. With Boiler Making, Mensuration of Surfaces and Solids, Rules for Calculating the Weights of Different Figures of Iron and Steel, etc. Elaborately illustrated. 8vo.....\$3 00

A Practical Workshop Companion for Tin, Sheet Iron and Copper Plate Workers. Containing Rules for describing various kinds of Patterns used by Tin, Sheet Iron and Copper Plate Workers; Practical Geometry; Mensuration of Surfaces and Solids; Tables of Areas and Circumferences of Circles, Japans, Varnishes, Lacquers, Cements, Compositions, etc. By Leroy J. Blinn. 100 illustrations. 12mo.....\$2 50

Galvanized Iron Cornice Worker's Manual. Containing instructions in laying out the different Meters, and making Patterns of all kinds of Plain and Circular Work. Also Tables of Weights, Areas, and Circumferences of Circles. By Chas. A. Vaile. Illustrated by 21 plates. 4to.....\$5 00

The above or any of our Books sent by mail free of postage, at the publication prices, to any address in the world.

Our large catalogue of Practical and Scientific Books, 37 pages, 8vo, and our other catalogues and circulars, the whole covering every branch of Science as applied to the Arts, sent free, and free of postage, to any one in any part of the world who will furnish us with his address

A SPECIALTY.

E. A. BELCHER,

Attorney-at-Law,

234 Montgomery St., San Francisco, Cal.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$2.00 post-paid. Sold by Dewey & Co., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

W. H. CONLY,

Mining, Commission.

SOLE WESTERN AGENTS FOR TYLER WIRE WORKS DOUBLE CRIMPED MINING CLOTHS.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing. Estimate furnished on application for wheels specially built and adapted in capacity to suit any particular case. Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globes Cases, from our cost, by applying to the manufacturers.

JAMES LEFFEL & CO., Springfield, Ohio, or 110 Liberty St., New York. FRASER & CHALMERS, General Agents, Chicago, Ill., and Denver, Col. PARKE & LACY CO., General Agents, San Francisco, Cal.

KROGH'S MINING HORSE-POWER HOIST

Is known to be the Best Horse-Power Hoist now made. It is strong and durable. The drum will carry 1000 feet of five-eighths steel rope. It can be used to run a pump or blower, in conjunction with hoisting. Manufactured by F. W. Krogh & Co., 51 BEALE ST., San Francisco.

WATER TANKS, WINE TANKS, CALIFORNIA WINE COOPERAGE CO. FULDA BROS., Proprietors, 30 to 40 Spear St., San Francisco. ALL KINDS OF CASKS, TANKS, Etc. SHIP, MINING, and WATER TANKS a Specialty.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and absolutely water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated. Price, \$2 each, or the entire instrument finished in gold plate, \$5. N. W. MOODEY, Fresno, Cal.

DEWEY & CO., PATENT AGENTS, 220 Market St., San Francisco, Elevator, 12 Front St.

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as The Safest and Strongest High Explosives in the Market. **GIANT POWDER or DYNAMITE,** Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE, which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safe in Handling. **JUDSON POWDER IMPROVED.**

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blast ing Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

Testing and Working Silver Ores

A VALUABLE BOOK. An illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope. Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working samples, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Pathe's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles Smelting, Mexican process, Chilean process, Kroll's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc. In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quick-silver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc. He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings, and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast. Price, post free, \$2.00. Sold by Dewey & Co., Publishers, 229 Market St.

INVENTORS, TAKE NOTICE!

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, June 4, 1891

It has been many years since the business community entertained a more hopeful feeling regarding the general outlook for a prosperous season than is now prevalent. The cool weather has insured a much larger grain crop than a month ago was thought possible, which with the certainty that prices will average from 20 to 30 per cent more than for three years past, inspires confidence that the various industries will be greatly benefited. To make the latter doubly certain, the large crop of fruit, hay, etc., is being marketed at good prices. The mining districts also report favorably. Present indications justify us in stating that the money which will be disbursed to farmers and orchardists this season will aggregate fully 100 per cent more than paid out for crops in the season just past.

MEXICAN DOLLARS—The market is quiet at 77@77½c.

QUICKSILVER—Receipts the past week aggregate 200 flasks, and the exports by sea 100 flasks to Mexico. The market is quiet but apparently steadier.

SILVER—Purchases so far in this month reported by the Department at Washington, aggregate as follows:

Date.	Offered ounces.	Purchased ounces.	Price paid per ounce.
June 3.....	944,000	329,000	\$.97

The market has not undergone any material change. Our advices indicate a more hopeful feeling of the metal, and acting on it, large operators at the East and in Europe are not disposed to press the market, but on the contrary are more reserved in their offerings. The late stringency in the European money markets was, it is said, taken advantage of by a moneyed clique, which bought all the gilt-edged securities they could whose value is largely contingent on that of silver. On this coast no perceptible increase in the output of silver is reported, but that in gold is said to show a slight gain.

BORAX—Exports by sea the past week aggregate about 1500 tons to New York. The overland shipments to the East are said to be quite large. There is an easier feeling in the market.

LIME—Receipts the past week aggregate 9385 bbls. It is reported that concessions are obtainable. The demand is unusually large for building purposes.

LEAD—The market is strong at an advance. The low priced poor stuff on the market, it is said, has been cleared up. The East is strong and higher owing to heavy purchases having cleaned up all pressing lots on the market.

TIN—Imports of plate the past week aggregate 14,987 boxes plate from Liverpool and 2400 boxes by rail from the East. The market for plate is barely steady. For pig the market is weak.

COPPER—The market has a stronger tone. New York mail advices report stocks accumulating and buyers offish. London cable to the *Iron Age* May 28 is as follows: Active speculative buying caused a further rise in prices of Copper early in the week, and while business has been on a smaller scale the past few days, there is yet a good consumptive demand that sustains the market.

IRON—Imports the past week aggregate 300 tons pig from London. There is nothing coming to hand from up north, the iron works in Washington and Oregon using the output. With us the market is weak and unsatisfactory. The very low freights from European ports to California admit of free shipments.

COKE—Imports the past week 1000 tons from England. The market is barely steady.

COAL—Imports the past week aggregate as follows: Tacoma 8,400 tons, Departure Bay 7,855, Sydney 3,300, Philadelphia 200, Coos Bay 1,150, Nanaimo 7,497, Hakodati 2,350, Seattle 1,100, Swansea 1,500, Newcastle, N.S.W. 1,220. Total 34,582. A reduction is noted in two brands. At \$9.00 a ton Wellington is selling for less than ever before in this market. The coast collieries are sending more coal to this market. This promises to be a season of universal low prices for coals. Our large wheat crop is attracting vessels, and not to come in ballast they accept very low freights. It is claimed that a vessel at Antwerp has been taken at 8s per ton for this port and this is the lowest freight on record from that port to this. This charter is given by us to show the influence on the coal market here.

Eastern Metal Markets.

By Telegraph.

New York, June 4.—The following are the closing prices the past week:

	Silver in Silver in London.	New York.	Copper.	Lead.	Tin.
Thursday.....	44½	97	13 00	4 32½	20 30
Friday.....	44½	96½	13 05	4 32½	20 40
Saturday.....	44½	97½	12 90	4 42½	20 70
Monday.....	44 5-16	97½	12 90	4 45	20 70
Tuesday.....	44 5-16	97½	12 90	4 45	20 70
Wednesday.....	44½	97½	13 00	4 45	20 80

Borax is steady at last rates. Quiksilver, 60¢/oz; fair trade. Tin is higher but easy at the advance. Lead is strong and more inquired for. Copper, although reported unchanged, appears to be working into better shape.

Our Agents,

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Mining Share Market.

The mining share market ruled heavy, with slight fluctuations throughout the past week, but this has been according to the prearranged program, so as to "freeze" all outsiders they can out of stock. It is still in the program to send prices to slightly lower figures, and then start a new deal. So as to facilitate outside selling, more assessments are in order. The writer still has faith in the market, and has good grounds on which to base his opinion that higher prices will obtain in this year than any time since 1886, but that we are to have a market is out of the question for so far nothing has been found lately in any one of the mines to warrant more than a deal. The writer has also good grounds on which to base the assertion that there are other stocks that will make a larger percentage to buyers than will Con. Virginia, although the latter will doubtless be used as a lever with which to handle the market for with it, it can be done to better advantage. The pool is using the summer vacation "racket" and other plausible cock-and-bull stories to destroy confidence so as to not only keep outsiders from buying but get them to sell, both of which they are doing to perfection. Nearly all who bought during the recent advance have sold out—many at a heavy loss. Of course they swear they will not buy again, but experience has taught the pool that the fools are not all dead. They throw out the bait and the latter rush in and with their money soon part. Who the pool will get to expert on the next ore development so as to sell stock, as they did in Con. Virginia, is not known. It would seem as if this method of victimizing outsiders has been played enough. Comstock superintendents experted on the Tuscarora district, reporting rich ore, etc., and Tuscarora stocks have not stopped going down from that time to date. A \$20 piece will pass current anywhere and the holder will not sell it for \$10. So it is in a mine, insiders are not apt to have a mine expected to sell stock, unless they have good reasons to believe that the ore in sight is not worth the market price of the stock.

The Supreme Court decision on trading in stock on a margin, was a God send to the pool, for by its publication they gained good lines of stock. The decision in question is good and will do no little in purifying the putrid air of Pine Street. It is one that all honest brokers should rejoice in, for it will bring honesty to the front, and in so doing will allay all fears now entertained by outside moneyed men in investing in stock. That part of the Constitution, on which the decision is rendered was evidently framed to prevent any knowing or underhanded way of doing business by a broker whose instincts are far from honest. It is well known that there are some broker firms that do not buy stocks for customers when they have reason to believe the market is going down. They report purchases, which were never made, and, vice versa, when ordered to sell stock and they have reason to believe that the market is going up. It is these that the law is aimed at. To bring the business within the confines of the Constitution and make the transaction a legitimate business one, there are two ways, viz: In all purchases of stock, the buyer or customer is entitled to and should know the number of the certificate of stock, date issued, from what broker purchased, and the price, and this stock is held by the broker for the buyer as collateral against all moneys advanced. The buyer can at any time come in and get by paying all claims against it, that particular stock. Again, the transaction can be closed by the customer giving his note for the remainder of the sum due. In this note drawn one day after date, an agreement can be incorporated that the stock held, giving number of certificate, can be sold when its market value falls below a certain percentage. Of course with clippers this cannot be done, but as they close their transactions almost daily, it is not necessary, yet even with them some kind of written agreement is best. By decision of the Supreme Court, proxy voting at election is a thing of the past, for a person can and should be prosecuted for voting stock not his own, although standing in his or her name as trustee. It is a good decision and all honest brokers should rejoice it has been rendered.

From the Comstock mine our advices are of a still more encouraging character and dealers will find that what we have said about rich ore in some of the mines, will be fully verified before many weeks pass. One or two mines whose shares are selling below \$2 or \$2.50 will come to the front before long. Con. Virginia battery assays are higher, as are Challars. That they can be made still higher as are Overman and other bullion-producing mines is not questioned by any one. The prospect work along the entire lode is of a very interesting and important character. It is more extensive and better systematized than for years. Good results are as certain to follow as the sun will rise on to-morrow. From the outside mines the news is of an encouraging character. In the Bodie district rich ore is being taken out for future milling, probably after an assessment is levied by the Bodie Mining Co. In the Tuscarora district, two or more of the mines have more bullion on hand than the stock is selling for; why it is kept back is a question and gives color to a report of a big deal soon in that district. From the Quiftoas nothing new is at hand.

L. C. MARSHUTZ

T. G. CANTRELL.

NATIONAL IRON WORKSN. W. Corner Main and Howard Sts., San Francisco,
—MANUFACTURERS OF—**Stationary and Compound Engines, Flour, Sugar, Saw
and Quartz Mill Machinery.****AMALGAMATING MACHINES. CASTINGS AND FORGINGS** Of Every
ALL WORK TESTED AND GUARANTEED.**IMPROVED PORTABLE HOISTING ENGINES.****NATIONAL ROCKER QUARTZ MILL.**

KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.
MARSHUTZ & CANTRELL, Sole Manufacturers.

The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

Send for Circulars and Price List.

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.

121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS, Varying from the fraction of 1 up to 15 and 20-horse power, unequaled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

THE PELTON WATER WHEEL CO., 121-123 Main Street, San Francisco, General Western Agents.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FRUE

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1886.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

Winding Indicator and Safety Hook.

Mr. John Bowen of Maldon, Victoria, has invented a winding indicator, which is in use in that Colony and which is described in the report of the Secretary of Mines. The engraving shows the operation of the device.

In the end of the winding-drum shaft *G* is tapped a screw *E* of the required length (according to depth of shaft). Upon this screw a square nut *D*, with corresponding thread, travels to and fro. Upon this nut the fork *C*, with slot, rides, and is kept in position by a pin in the nut *D*. The fork *C*, in connection with the rod *S*, supported by two standards *RR*, reaches the pointers *AA* on the face of the indicator, which are adjusted by set screws. The pointer next the drums is adjusted to the various levels in accordance with the loose drum.

The senior Inspector of Mines, Mr. Nicholas, in his report on the indicator, says: "This indicator is simply constructed and is accurate in its work. It is erected immediately in front of and in close proximity to the engine-driver. The signal or alarm bells strike sharply and distinctly, and so direct the attention of the driver. It is an economical and useful indicator."

Mr. Bowen has also invented a safety-hook, which is described as follows:—Figure 1 of the cuts shows the outer plate or casing; Figure 2 the eccentric plates, of which there are two, and which are placed within the outer plates and secured by a center-pin passing through each plate. To secure the top shackle, the openings *A, A* must be brought opposite to each other and the pin dropped into the openings. The eccentric plates are then pressed to the right and left, when the pin of the shackle

SAFETY HOOK FOR HOISTING WORKS.

INDICATOR FOR MINING SHAFTS.

passes along to the extreme end of the slot *D*, and the shackle is secured. In a case of overwinding, the shackle passes up through the ring or circular opening in the plate *G, G* Figure 4, with which the wings *E* will come into contact, when the shackle-pins will travel along the slots *B* and *D* at bottom and top of the eccentric plates, and at the same time bring out the wings *F*, which are instantly secured on top of plate *G, G* by the pin of the lower shackle falling into the drop *C*, thus securing a suspending hook and cage, which can only be released by taking off the weight and lifting the shackle-pin out of the drop *C*. Figure 3 shows the hook closed, and Figure 4 the hook after having passed through the circular opening in plate *G, G*.

THE present annual production of fuel in Great Britain is 180,000,000 tons. It is calculated on the lowest basis that the proposed eight-hours day would diminish this production down to 162,000,000 tons, and many of the owners believe that the output would be reduced from 20 to 25 per cent. The manufacturing industries of the country consume something like 100,000,000 tons of the present output, which is less than sufficient for their demand.

A NEW amalgamating machine, to go on the Rae dredger on the Carson river, is shortly expected. It has a capacity of handling 500 tons per day. The river mining machine will soon be given a practical test.

DURING last week the Dexter Mining Company of Tuscarora shipped five bars of gold bullion, valued at \$15,000, the product of a 30 days' run with five stamps at the De Fries mill.

CORRESPONDENCE.

We admit, unadvised, opinions of correspondents.—Eds.

Mines of Lemhi Co., Idaho.

EDITORS PRESS:—Considering the extensive mining developments, which are at the present time being so profitably pushed forward in both North and South Idaho, a few items on the outlook of a central portion of this great mining State may be of interest to your readers.

Lemhi county is situated on the western slope of the Rocky and Bitter Root mountains; is bounded on the east by Beaverhead county, Montana, and extends about 150 miles north and south by 100 west from the divide. Salmon City is the county seat, from where there is a daily stage running to Red Rock, on the Utah Northern R. R. Since 1866, Lemhi has produced, according to official reports, \$16,000,000 in placer gold, which, by the way, is a big recommendation to a county, coming as it did from shallow digging surrounded by a primary formation, and there still remains large areas of ground that could be made to yield handsome returns by the intervention of capital. The Lemhi river, which is a stream flowing not less than 5000 inches of water 30 miles above its mouth, at its lowest stage, runs along the base of the Rocky mountains for 60 miles only separated from the same by a stretch of low, rolling alluvial foothills about six miles in width which it has evidently been the means of forming.

Gravel Claims.

Trending down through these foothills from the rocky peaks of the main range, are numerous small creeks, nearly all of which, after they leave the narrow canyons, and enter the secondary formation, carry a good hydraulic prospect that only need a big head of water to make them profitable mines. Most of these streams have been worked in a small way for the past 20 years. The one that has produced the most gold is known as Bohannan Bar, situated eight miles above Salmon City. There has been about 150 acres of this gravel worked, that paid on an average \$5000 per square acre, and the bar still contains 1500 acres of the same quality. The gold is worth over \$18 per ounce, of the thick-scale order, scattered all through the gravel, with small nuggets on bedrock.

The bar constitutes an even stretch of ground nearly one-half mile wide by six miles long, with good grade. The gravel will average about 16 feet deep, with soft sediment bedrock that can be piped right into the flume, and no boulder but what will run right through a small flume.

From the natural advantages surrounding it, this gravel could be run off very rapidly with a big head of water. There has been a survey made, and it would take a ditch about 40 miles long from the Lemhi river to cover the ground. The route is quite feasible—good digging nearly all the way, and with the exception of two or three deep gulches to be piped or flumed over, does not offer any serious engineering difficulties. If this ditch were constructed as far as Bohannan creek, and then extended eight miles farther, it would cover two other creeks, one having an estimated area of 1000 acres and the other 500, the kind and quantity of gold on these properties being about the same as Bohannan and the conditions of its occurrence similar. Each one of these creeks is being profitably operated at the present time.

Water Supply.

It is only for a short time when the snow is melting that there is sufficient water in these streams to do any good; then each claim works about six men and pipes off from two-thirds to 1½ acres. These creeks are extensively developed from one end to the other by shafts, bedrock tunnels and patches worked off, and the value of the gold they contain could be quite accurately and easily estimated, and, it would seem, offers a big inducement for the investigation of heavy capitalists. The ground is held in 160-acre tracts by parties residing in this country and could be bought up at a very reasonable price per acre.

A Mountain Basin.

From Salmon City it is just 15 miles due west across the mountains to the town of Leesburg, which is the dilapidated remains of a once populous placer mining camp situated in the center of an elevated mountain basin of that name 7000 feet above sea level. The basin shows evident signs of glacial action, which has doubtless been an important factor in grinding out the precious metal from its parent lodes. It is about 15 miles long by 6 across, with gulches putting in from all directions. These diggings were mostly shallow and yielded up their dust very readily. The stream was taken off during the first few years after their discovery and the ground has nearly all passed into the hands of Chinamen, who make a good living handling over the old gravel piles and gouging around for rooker dirt. This basin has produced not less than \$12,000,000 since 1866. The bedrock is mostly decomposed granite and talc slate. There are dozens of large and small quartz veins cropping out around the heads of the gulches; some of them look very promising and give a fair prospect in free gold, but there has been very little development work done on any of them.

The main stream that drains this basin is known as Napier creek and runs very flat until it passes through a narrow gap in the

mountains, there taking a plunge of about 2000 feet in less than two miles; just before this creek enters the canyon there is a claim called the

Bull of the Woods.

It was originally the site of a shallow lake, and doubtless acted as a catch-pot for a good deal of the gold that passed over the falls. The reason why this ground was never worked is because the bedrock in the canyon is higher than it is farther back up the creek, and consequently needs quite a long bedrock tunnel to drain it, which none of the early diggers cared to tackle. There was an attempt made to drift the ground. They sunk a shaft to bedrock eight feet square near the upper end of the claim that produced \$120 in heavy gold, but in going down they passed through a stratum of quicksand, which it was impossible to keep out, so they had to abandon the attempt. The ground above this claim where bedrock was first struck, paid an ounce a day to the man to ground sluice.

There is also a bar running down one side of it that was very rich. The bedrock to be driven through to drain this ground is a soft viscid conglomerate, and ought to work easily. This property can be purchased for a reasonable figure. It comprises 320 acres, is covered by U. S. Patent and owned by Mr. Fred Phillips of Challie, Idaho. Below the falls Napier creek runs off comparatively flat again for about two miles until it joins Big Creek. Above the junction there is another 320 acre tract located. It has a shaft down 21 feet, which shows a bank of fine red gravel with a good hydraulic prospect from grass roots increasing in weight as depth is attained; but they have not got bedrock yet. The gold is precisely the same as that found in the basin above. This property is held at the present time.

The Tabor Investment Co.

Below the mouth of this creek 10 miles on Big creek is situated the property of the Tabor Investment Co. of Denver, which was purchased last January from David Lamont, et al of Dillon, Mont. The company have 40 men employed at the present time under the efficient management of Mr. W. H. Patterson. Their object is to get bedrock in the basin of the main creek, to thoroughly prospect the ground, and find out what they have got before bringing in any more machinery.

They also have an extensive bar area on both sides of the stream, on which there is a crew of men drifting and taking out money right along. The gold is coarse nearly all small flat nuggets and fine in quality. It is the theory of old miners who have worked on the bars and tributaries of this stream that if they find rough bedrock in the main channel it will be fabulously rich, and judging from the nature of the formation that crops out and the bedrock of the bars, it will be as rough as they desire. The manager, Mr. Patterson is a veteran placer miner and will doubtless come as near engineering the venture to a successful issue as any one could.

The Moose Creek Claim.

We will now retrace our steps back to Leesburg, and notice the Moose Creek claim, which is situated on the main stream of a twin basin to Leesburg, that branches off in a northerly direction. The outlet of this basin is also flat, but the creek runs parallel for a little way with a deep gulch separated only by a low narrow divide which only required cutting through with a short tunnel to give a dump of 500 feet deep. This claim is owned and operated by Mr. D. McNutt, who has taken out over half a million of dollars since he came into possession. The pay channel is about 300 feet wide and from 10 to 18 feet deep small gravel with soft granite bedrock. The gold is of extra fine quality being worth a trifle over \$19 per ounce, shaped like coarse gun powder, and is quite heavy and easily available. The ground is worked with a 4 foot bedrock flume and a six inch hydraulic giant using over 500 inches of water under a pressure of 160 feet, and there is ground enough ahead of the out to last for 50 years. A great drawback to this property has been their difficulty in controlling the water during the spring rise. The basin is covered with a dense growth of black pine timber which at this altitude holds immense banks of snow until late in the spring. Then for a while the creek will run as much water as a good sized river. If there was a large reservoir formed (for which there is an excellent site) so as to keep the surplus water from running to waste, and thus extend the piping season, the yield of gold could be enormously increased and the claim made very profitable. Mr. McNutt is one of the original pioneers of this country, and consequently getting pretty well along in years and unable to give the property the personal attention it requires, and will sell if the right man comes along and means business. It is a fine opening for any one on the lookout for a big gold mine investment.

Gold Quartz Boulders.

In traveling over the mountains, back to Salmon from Moose creek, the wagon road passes by a very peculiar deposit of free gold quartz, right on the highest divide, 9,000 feet in altitude. It is known by the euphonious title of the Snow Fly mine, and consists of a mass of float boulders, of all sizes from a pebble up to one that roughly squared 20 feet, promiscuously scattered over about three acres of ground, these were broken up and worked in a five-stamp water-power mill built for the purpose down on the creek. It is a red-stained quartz of a granular texture perfectly free milling and gave an average yield of \$50 per

ton. The mine has produced \$80,000, nine-tenths of which was taken from the boulders. There is very little development on this property under the surface, they sunk a shaft about 60 feet deep and found a 3-foot vein of the same kind of quartz, only not quite so rich. At this depth, the shaft made water rapidly which they were unable to handle and had to quit the operation for lack of capital. If they should happen to run on to the chimney that produced those huge boulders while doing their annual assessment work it will prove a veritable bonanza of free gold quartz, this property is owned by Messrs. Hogan & Phillips of Salmon City.

Salmon City.

Is beautifully situated in a level valley, at the confluence of the Salmon and Lemhi rivers, surrounded by a fine farming and grazing country, where grain, vegetables and small fruits grow to perfection.

The Lemhi has an average grade of 50 feet to the mile which affords excellent irrigating advantages, and could be made to yield almost unlimited water power for any purpose required.

From the carboniferous limestones at the south end of the county in which the sand carbonate deposits of the Viola mine have been so profitably worked, to the Kentucky free gold mine which is successfully operated to a depth rapidly approaching 1000 feet, in the granite at the north end of the county, there is as fine a natural section of "geological horizons," plentifully sprinkled with their usual associated ores, as it would probably be possible to find anywhere.

Unprospected Regions.

From the Kentucky mine, west 100 miles by about 100 miles north and south, flanked by the world famed placer camps of Florence, Elk City and Warrens, in Idaho county, there is a stretch of country practically unexplored for quartz, which offers an exceptionally fine field for prospectors.

This section of country, like most other bullion-producing, has been victimized by a class of "lake" mining operators and promoters who have given it quite a setback. Their principal stock in trade is a slick tongue and an utter disregard for the confidence placed in them. We don't have any special antipathy for the genus "Middleman," provided he understands his business and is willing to act square, as such men are a boon to any undeveloped country; but I think if investors would look a little into the credentials of mining promoters and shy off from those of shady reputation, they would save themselves many a disastrous investment.

The air is thick here with rumors of railroads that are calculated to pass this way. If they would only quit "rumoring," and materialize, they would find here a country capable of a wonderful development and furnishing an extensive traffic.

We have abundance of wet lead ores, dry silver ores, some mammoth outcrops of copper and iron; extensive tracts of the finest timber, water power in abundance, and every essential (with the single exception of transportation facilities) necessary to make a prosperous bullion-producing country, which, judging from an extensive experience and personal observation, will compare favorably (at the surface) with some of the best-developed mining districts in the Northwest.

Salmon City June 4, 1891.

Oro Blanco, Arizona.

EDITORS PRESS:—There is but one reason to show why the Yellow Jacket should be or is a larger mine than others on the same lode, and that is, there is more work done to develop it as such. Upon the surface this mine does not show as much or as high-grade ore as some of her sister claims.

On the northerly end of the above mine the surface is cut up by a good-sized canyon, which passes through the ground transversely, showing plainly a split in the ledge, and supposing the Yellow Jacket the lower stem thereof the northerly extension would form a plain letter Y; the easterly branch of said letter still containing principally gold, while on the westerly arm silver predominates.

The first northerly claim on the westerly branch ledge is owned by John Bartlett, and although it has but a 15 foot shaft, shows up a large ledge of gold and silver bearing ore.

The second claim on the same branch is the property of H. F. Diehl, and shows up a large deposit of silver-bearing ore. On this claim can be found some high-grade silver ore, as easy therefrom running as high as \$25 an ounce per ton. Five tons of ore shipped from this claim netted the owner a little over \$600, the sampling works assaying being 195 ounces per ton. Allowing \$50 per ton for transportation and treatment, and deducting the percentage of New York quotations generally allowed, you have the above net proceeds.

This claim has a 50-foot shaft off the ledge at the bottom of which there is a 65-foot cross-out, with which it is intended to tap the ledge as soon as possible. On the surface there is a four-foot ledge that will average 30 ounces silver per ton not including the higher grade of ore.

The first extension on the easterly branch of the Yellow Jacket lode is known as the Christinas Gift claim, owned by H. F. Diehl. This claim is principally gold bearing and has a 25-

foot shaft showing about eight feet of ledge matter, assaying from \$15 to \$25 gold per ton. There is ore all along the surface. The full length of this claim shows up well for the opening up of a large low-grade gold property.

The second location owned by the same party has no development work done as yet but shows similar to the above claim on the surface.

The next piece of property and the last of which I shall speak on the northerly extension of this lode is the Yellowstone mine also owned by H. F. Diehl.

There is a 50-foot and a few 10-foot shafts on this claim, showing in either place a ledge from five to eight feet in width of gold-bearing ore. The 50-foot shaft is five by seven feet, shows ore the full width and no hanging wall. Assays from this claim run from \$25 to \$30 gold per ton, and specimens assaying over \$700 gold per ton have been found. I think it safe to estimate the average of this ore to be, say \$20 gold per ton; also about five ounces silver.

The same plea for not further developing the above claims, is here given, that was spoken of in my former penning: No capital, together with the fact that about a year ago the owner was obliged to buy out his partner in order to hold the property, which cost him several thousand dollars, which has out short his development powers.

Here are a group of four or five claims in close proximity to one another, worth the attention of good business men and mining capitalists, as I am reliably informed the owner thereof is willing to risk his claims in having them further developed, and will give reasonable terms either for cash, purchase or bond.

The mining industry of to-day holds within itself more reliable and inexhaustible elements of success than at any former period of its existence, and the fact that it has not heretofore met with its merited portion in these parts, is owing to a lack of honesty and proper management by former representatives, or more properly termed, manipulators of capital, a too well-known fact to other parts of the mining country as well as here, to make further mention of.

This is by no means the extent of mining properties of value in Oro Blanco district, and in my next I will speak of other claims deserving of mention.

I. C. U.

Cyanide in Amalgamating Gold.

EDITORS PRESS:—The article of Mr. C. H. Aaron, in your issue of the 25th of April, has just come under my eye.

Many years ago an Englishman, who had acquired his experience in Columbia, brought to my attention the advantage to be derived from the use of cyanide of mercury with cyanide of potassium solution in pan amalgamation of gold.

Some time after, being engaged in milling by battery amalgamation, where the loss of gold was excessive, not to be corrected by any usual means, and scarcity of water compelled the saving of water and its continuous use, I experimented with the cyanide of mercury and found excellent results, not equal to those described by my English friend as resulting from its use in pans, but such as made a very important difference in the "cleanups." My recollection is (I have not the memoranda by me) that the saving in comparison with "oar samples" was raised from about 55 per cent to about 73 per cent.

I used habitually when milling under similar conditions (using water continuously) to make the pulp slightly alkaline by use of soda, with excellent results. The same use of an alkali was made during the experiments with the cyanide of mercury.

Lincoln, N. M.

Mining and the World's Fair.

EDITORS PRESS:—In speaking of the California World's Fair Commissioners in your issue of May 16th, the error is committed of stating that the mining industry had received no recognition in their appointment.

Mr. Robert McMurray from the 2d Congressional district is an old Nevada county miner for many years superintendent of the Enreka Lake Water and Mining Co., and now largest owner and manager of the famous Delbi gold-quartz mine.

Mr. John Daggett, of the 1st district, who commenced mining in El Dorado county in 1852, and has been constantly engaged in that industry since—spent two years in Nevada, superintending silver mines and mills, and three years in Calico, San Bernardino county—is now principal owner and manager of the Black Bear gold-quartz mine in Siskiyou county.

Mr. Irving M. Scott of San Francisco, although not a miner, is at the head of one of the largest manufacturing of mining machinery in the United States; and I can say for the balance of the commissioners, that they are fair-minded men of liberal views, and desire to see every interest and industry of California well represented at the Columbian Exposition.

MEMBER.

THE Plumas National says that the Shenandoah Mining Co. has just contracted for a ten-stamp mill upon its mine in French ravine, near Rio Bar.

The New Road Law.

In response to a quite general demand on the part of our readers for the new road law, we give the following transcript, prepared by the Santa Rosa Republican. The sections are amended as follows:

2641. The Boards of Supervisors of the several counties shall divide their respective counties into suitable road districts, and may change the boundaries thereof, and each supervisor shall be ex officio road commissioner of the several road districts in his supervisor district, and shall see that all contracts made with, and all orders of the Board of Supervisors pertaining to the roads and bridges in his district are properly executed; provided, when in any county the members of the Board of Supervisors thereof are not elected by districts, it shall be the duty of such Board, by proper order, to be entered in its records, to divide such county into supervisor districts, to correspond with the number of members of such Board, and assign to each member thereof one of such districts, of which he shall be such Road Commissioner.

2642. From and after Monday following the first day of January, A. D., eighteen hundred and ninety-three, the office of Road Overseer shall be abolished; provided, that whenever in this Code the words Road Overseer occur, they shall be taken and construed so as to read Road Commissioner.

2643. The Boards of Supervisors of the several counties of the State shall have general supervision over the roads within their respective counties. They must, by proper ordinance:

1. Cause to be surveyed, viewed, laid out, recorded, opened and worked such highways as are necessary to public convenience, as in this chapter provided.

2. Cause to be recorded as highways such roads as have become such by usage or abandonment to the public. Also, all such streets and roads as have been or may be declared such under section seventeen hundred and sixty-four of the Code of Civil Procedure.

3. Abolish or abandon such as are not necessary.

4. Contract, agree for, purchase, or otherwise acquire the right of way over private property for the use of public highways, and for that purpose institute or require the district attorney to institute proceedings under title seven, part three, of the Code of Civil Procedure, and to pay therefor from the district road fund of the particular district.

5. At the first regular meeting in January, eighteen hundred and ninety-three, and at any regular meeting thereafter, advertise for sealed bids for keeping in order, and repair all such roads, culverts and bridges in the county, as hereinafter provided; provided, that, the Board of Supervisors, in their discretion, may exclude from such contracts the repairing of any or all bridges.

6. In case no bids for contracts are received or accepted for work in any district, the Board shall order the work to be performed by the Road Commissioner of said district, as provided for in section twenty-six hundred and forty-five of this Code.

7. If any contractor neglects or fails to perform any work provided for in his contract, the road commissioner of the district in which such neglect or failure occurs shall notify such contractor to immediately make such repairs or do such work as is needed; and if the contractor does not use reasonable diligence in complying with such notice, the Road Commissioner shall cause such work to be done by others, and the cost of such work shall be deducted from the quarterly allowances of such contractor.

8. The Road Commissioner, in all the road districts in his supervisor district, shall inspect the work done under such contracts and orders and make a written report thereon to the Board in January, April, July and October of each year, which report shall include the amount and kind of work ordered done by him during the preceding quarter, under the provisions of subdivision seven of this section. The Board shall thereupon cause the amount found due the contractor for the preceding quarter, less such sums as the Road Commissioner may have necessarily spent by reason of the neglect of such road contractor, to be paid to such contractor, from the funds of the road district embraced in his contract.

9. The Board shall cause to be kept a book showing the number of sections in each district, their boundaries, length of roads in miles and fractions of miles, names of contractors, amounts of contract, and the cost of maintaining the several sections of road in each district.

10. Levy a property tax for road purposes.

11. In their discretion, cause to be erected and maintained, on the highways they may designate, mile stones or posts, or guide posts, and guide posts properly inscribed.

12. Cause the road-tax collected each year to be apportioned to the several road districts entitled thereto, and kept by the treasurer in separate funds.

13. Audit all claims on the fund of the respective road districts, when required to pay for improvement thereon.

14. In their discretion, they may provide for the establishment of gates on the public highways, in certain cases, to avoid the necessity of building road fences, and prescribe rules and regulations for closing the same, and pen-

alties for violating said rules; provided, that the expense for the erection and maintenance of such gates shall, in all cases, be borne by the party or parties for whose immediate benefit the same shall be ordered.

15. For the purpose of watering roads in any part of the county, the supervisors may erect, maintain waterworks, and for such purpose may purchase or lease real or personal property. The cost for such waterworks and the watering of said roads may be charged to the general county fund, the general road fund and the district fund of the district or districts benefited thereby.

2644. This section is hereby repealed.

2645. The Road Commissioner, under the direction and pursuant to the orders of the Board of Supervisors, must:

1. Take charge of the highways within their respective districts, and by and with the consent and approval of the Board of Supervisors shall employ all men, teams, watering carts and all help necessary to do the work in their respective districts, provided that no Road Commissioner shall be interested, directly or indirectly, in any contract or work to be done in the road districts under his charge and control.

2. Keep them clear from obstructions and in good repair, and destroy or cause to be destroyed, in the months of July and August of each year, all thistles, Mexican cockleburrs, or cockleburrs of any kind, and all noxious weeds growing or being on any portion of the public highways or public roads in their respective districts, provided that there be no contract to that effect.

3. Cause banks to be graded, bridges and causeways to be made, where necessary, keep the same in good repair and renew them when destroyed, provided that an emergency exists, or pending the awarding of any contracts.

4. Make quarterly reports, under oath, of the number of days they have been employed during the preceding three months, the number of days' labor performed on the roads and highways in their respective districts, by whom performed, and the wages paid per day; filing therewith a receipt or receipts, signed by each or all persons who have performed labor, stating the number of days' labor performed, and the amount received for the same; also the amount and value of the materials and the kind of each thereof.

5. When not otherwise provided for by the law, he shall receive for his services as such Road Commissioner, twenty cents per mile one way for all distances actually traveled by him in the performance of his duties; provided that he shall not in any one year receive more than three hundred dollars.

6. The Boards of Supervisors of each of the several counties may, if they deem it to the best interests of their respective counties, appoint one Road Inspector for each such county, and prescribe his duties and compensation, subject to the provisions of this act, provided that the compensation of such Road Inspector shall not exceed the sum allowed by law as the total compensation for the Road Commissioners of such county. In case such Road Inspector be appointed, no salary, fees or compensation shall thereafter be allowed to said Supervisors as Road Commissioners during the time that said Road Inspector is serving as such. The salary, fees or compensation of such Road Inspector shall be paid from the county road funds, and shall be as nearly as possible apportioned among and paid from the road district funds, according to the amount of service performed by him in the several road districts of the county.

Said Boards of Supervisors may delegate to said Road Inspector all powers conferred upon them by law as Road Commissioners, save that said Boards of Supervisors shall not delegate to said Road Inspector any power or authority to open bids, or award contracts, as provided in this Act, and no Road Inspector shall be directly or indirectly interested in any such contract.

2646. The Board of Supervisors must:

1. Advertise for sealed bids to maintain the roads in the several districts in the county, where contracts have not already been let, or for the reletting of contracts, by notice in a weekly paper published in the county, or in one published within the district in which the work is to be done, if there be one so published, and also post three notices in prominent places within said district, for four consecutive weeks immediately prior to the day set for receiving and opening said bids and awarding contracts.

2. The notice shall contain a general description of the roads in the district in which the work is required to be done under said contracts, the boundaries of the district, and explicit specifications as to the manner in which the work shall be done in particular parts or portions thereof.

3. The bids shall be made and contracts awarded for a term of not less than one nor more than four years. They shall be opened and the contracts awarded at any regular meeting.

4. Said contracts shall be awarded separately for each road district in the county and no contract shall be awarded to a person who is not a qualified elector of the county.

5. Contracts shall be awarded to the lowest responsible bidder, and a bond caused to be executed in a sum equal to the amount of the contract for the faithful performance of the conditions of said contract. The contractor shall also be required to perform the duties described in subdivisions two and three of section 2645 of this chapter.

6. The Board may reject all bids.

2652. The Board of Supervisors may, an-

usually, at any regular meeting held between the first days of January and March of each year, levy on each male person over 21 and under 55 years of age, found in each road district during the time set for the collection of said poll taxes for that year, excepting all persons who were honorably discharged from service in the army or navy of the United States, at any time within the first day of April, in the year of our Lord 1861, and the first day of September, in the year of our Lord 1865, an annual road poll tax not exceeding three dollars; and from every such person not above excepted, in a road district, who has not paid the same in some other district, must be collected the amount of road poll tax so levied.

Said road poll tax shall be collected by the County Assessor in the same manner that State poll taxes are collected, and all remedies given by law for the collection of State poll taxes, shall apply to and be in force for the collection of road poll taxes.

Road poll tax receipts in blank, signed and numbered in the same manner that other poll tax receipts are signed and numbered, shall be delivered by the Auditor of the county to the County Assessor on or before the first Monday of March of each year; and said Assessor shall be charged with the amount of such road poll tax receipts delivered to him, and he credited with those returned, and shall settle with the Auditor, and pay over the amounts collected, in the manner provided in section 3553 of this Code.

A sum not exceeding 35 per cent of all the road poll taxes so collected may be apportioned to the General Road Fund, and the balance shall be apportioned to the several districts of the county from which the same was collected.

Section 8. All Acts and parts of Acts in conflict with this Act are hereby repealed.

Section 9. This Act shall take effect and be in force from and after the Monday following the first day of January, in the year of our Lord 1893.

Opals.

At the last meeting of the California Academy of Sciences, the following paper was read by Melville Attwood, M. E.:

The precious, or noble, opal is one of the most beautiful gems in nature. When held between the eye and the light, it appears of a pale milky-reddish blue, but when seen by reflected light, it displays all the colors of the rainbow.

Opals are always cut *en cabochon*, on both sides, and the true beauties of the gem only display themselves when the stone is moved about, as then a fine opal really appears to have an actual life within itself.

Fine stones of a large size are rarely found; they seldom exceed an inch in diameter. When held in the hand to impart warmth to the gem, it is much more brilliant.

Some varieties of opal (the common) are found with silica and blends in metalliferous veins. They also occupy the interior of fossils in sandstone. Its formation is due to the solubility of amorphous silica in water, especially in hot water, or water containing carbonic acid, the silica being dissolved out by spring waters from decomposed silicates, and deposited under favorable circumstances in a state more or less approaching to purity.

At a former meeting I presented the Academy with opals in the matrix from the State of Washington. Since that I have sent another microscopic section of the Washington rock, which I now donate to the Academy. The section shows the rock to be basalt, consisting of a mixture of fine grains of labrador, feldspar, augite, etc., with a small quantity of magnetite iron.

Through the kindness of Adolph Sutro, Esq., I am now enabled to give the Academy specimens of opals in the matrix from Mexico, Australia and Hungary.

The inclosing rocks of those from Mexico and Australia are so altered, or decomposed, that I could not cut a satisfactory section from them. They are, however, without doubt, trachytes. The two specimens from Hungary are very interesting, being the same rock, but the one much altered or decomposed and the other fresh or unaltered. From the latter I managed to cut a section sufficiently thin to prove it to be a trachyte, with small crystals of leucite in it.

The result of my examination of the inclosed rocks of the different precious opal deposits, and from all the information I can obtain by papers written on the subject, is that the precious opals occur, or are found, mostly in dykes of intrusive volcanic rocks, and in those parts of the dyke near the surface, and where the rocks are greatly altered or decomposed.

MINERS OUT OF WORK.—A press dispatch from Helena, Montana, states that the last of the employees of the great Anaconda Mining Company have been discharged, even to the watchman, and the company mines at Butte and the mammoth smelter at Anaconda are shut up tight. More than 3000 men are thrown out of work. It was announced that the trouble was a dispute with the Montana railway over freight rates, and Marcellus Daly vouchsafed the information that work on a new line of railroad would begin at once, which may or may not mean that the works will not resume until the road is finished. Anaconda is a dead town and Butte is crowded with idle men, all because of the shut down.

To Sound the Pacific.

It has been definitely decided by the Navy Department to use the ship *Thetis* to survey the route for a cable to Hawaii. The soundings will be made from San Francisco to Honolulu. She will begin work just as soon as the appropriation for that purpose becomes available, which will be July first, and the work will be completed in two or three months. Lieutenant-Commander Glover, the hydrographer, says that since the *Tuscarora* took soundings 15 years ago, there has been considerable diversity of opinion as to the proper intervals between deep-sea soundings to ascertain the topography of the bottom of the ocean. After giving long and careful attention to this matter, Lieutenant-Commander Glover has devised a system by which soundings will be taken at intervals of one and two miles alternately, except when shoals are discovered, when soundings will be taken every quarter of a mile or even less if necessary. This plan will be employed by the *Thetis*. The *Tuscarora*, in 1875, found a shoal or submarine mountain in latitude 33 deg. north, longitude 132 deg. 30 min. west. At this point (near the California coast) a depth of 2282 fathoms ranged rapidly upward to 388 fathoms. The *Tuscarora* found that the greatest depth in the Pacific was along the coast of Japan, at some points there being a depth of more than five miles. A piano wire having a length of five miles was lowered, but failed to touch bottom.

Admiral Belknap, in an article in a Japan paper giving a description of his survey work, doubts whether a cable could be laid in such great depths. But a more feasible route might possibly have been found within 100 miles north or south of the point where this sounding was made.

Mr. Glover says that piano wire is admirably adapted for this work, and will be used by the *Thetis*. On the end of the wire will be an iron plummet, so arranged that the very moment it touches bottom it will become detached, and the relaxation of the wire's tension, however slight, is recorded on a delicate instrument on the ship's deck. An iron cup is also attached to the end of the wire, and this brings up a handful of sand, gravel, or whatever formation lies at the bottom.

Outlook on the Comstock.

The *Virginia Enterprise* says: Some people give up and "quesal" and some don't.

There is absolutely no cause for complaint at this end of the line. Many of us have engaged in the maelstrom of stock dabbling—sometimes called speculation—and we have emerged in vastly different conditions. Some came out untouched, some purified as if by fire, and many more came out badly battered, but still in the ring. But by this time we all should be pretty well trained to know how to take our medicine.

So far as stock gambling is concerned, it matters but little whether we guess them right or wrong. Those who guess them right don't invest among us. They go to Europe, or California, or the East and invest, and if they return after many years, it is a positive sign that they are broke.

So far as the business men of this community are concerned, they are all right. We will positively have a heavy season of work. Con. Cal. & Va. will extract from 2,400 to 2,800 tons of ore weekly until ice clogs the wheels of the river mills; the Nevada mill will run the year round; the Justice and Alta mills will have a long and steady run; the Occidental mill, we predict, will be started before long; the Yellow Jacket is experimenting on its gold bearing rock below the 1,200 level, and will ship about 100 tons of ore daily to the end of the season; the tailings mills on the Carson river are all at work. Savage and Overman will produce ore until next winter, and Hale & Norcross, Balcher and Crown Point will probably fall in line before the milling season is over.

So much work and activity means a fair business year, mattering not whether stocks go up or go down.

SHE RUNS THE MINE.—Mrs. Ed C. Loftus of Sonora, this State, has the distinction of following a line of business that few women know much about. She is a mining superintendent, and said to be a thoroughly competent one. She does not really follow the profession regularly, but only while her husband is absent attending to other business. The Golden Gate mine is said to yield \$168,000 net yearly. In referring to his wife's management, Mr. Loftus, who is stopping at the Occidental hotel, said: "Well, I must confess that she knows more in some respects than I do about mining, and I've had something like 20 years' experience in the business. It was my wife that advised me to take the property in the first place, even when it looked to be a risky venture, but I'm not sorry now I took her advice. She's just about as good a manager as myself, and if anything should happen to me, she could work that mine, and perhaps make more out of it than I can."—*Examiner*.

LATER developments in the Hirsch mine, Rens District, are even better than recently promised, and the outlook for the future is most encouraging. Regular carload shipments of rich ore are being made.—*Inyo Index*.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

NORTH STAR.—*Dispatch*, June 6: At the annual meeting of the stockholders of the North Star Co. held at Sutter Creek on the 3d inst, all of the difference between the company and the owners was adjusted and the mine will at once be reopened and work resumed. The old bond on the property had expired and the owners at first were not willing to give a new bond so favorable to the company, but finally agreed to. Both owners and stockholders have great confidence in the property and will start anew with renewed vim. The Comet is also to be prospected through the North Star.

SOUTH EUREKA.—*Amador Ledger*, June 6: The sinking operations at the South Eureka have reached a depth of about 30 feet. Nearly all the hoisting and other machinery purchased from the Ilex mine is on the ground. At the Hardenberg the mill is kept running steadily. No general cleanup has been made as yet, but the appearance of the plates gives every reason to hope for a paying output.

Calaveras.

PIONEER.—*Mt. Echo*, June 4: Work on the Pioneer mine, owned by Hallock & Co., is progressing rapidly. The shaft is now about 60 feet deep and the ore being taken out is of a very high grade. Mr. Hallock, the superintendent, is a mining man of great practical experience and a thorough metallurgist.

GRIDER.—Operations will soon be commenced on what was known in earlier days as the Grider mine, which is located on Smith's Flat. This mine was discovered more than 25 years ago by John Grider, but as he was not a man of means he failed to develop it to any great extent. The present parties have the money to work the mine and will no doubt succeed. There is not the slightest doubt as to the paying qualities of the mine if properly managed.

WEST POINT.—Away up in the quiet little burg of West Point things are very lively. The mines are running in full blast and turning out rich rock. Three or four loads of machinery passed through town on the way to the Lone Star (the Reed & Hillary mine). The quartz mills in this vicinity are kept busy crushing rock. Paddock & Morris had eight tons ground; the returns were about \$3000. The Barsley Bros. just had 18 tons ground. It turned out more than they expected. It is currently reported that a San Francisco company of large means will begin operations on the Brunner mine near Albany Flat in a few weeks.

El Dorado.

RUSSIAN DIGGINGS.—*El Dorado Republican*, June 6: S. A. Lane came down from Russian Diggings last Friday afternoon and went below on Saturday. Mr. Lane reports mining matters a little quiet in that direction at the present time. There seems to be some excitement about timber land which may be of value to Mr. Lane and his company, as they own 320 acres of mineral land most of which is covered with fine sugar pine and other valuable timber. They have their tunnel in 900 feet. Four hundred feet from the mouth of the tunnel they struck a rim channel of cement gravel three feet thick and 100 feet wide, all bearing gold. After passing through this first bed of gravel, the bedrock seems to pitch down several feet below the level of the tunnel. After running 400 feet farther through a white lava cap, Mr. Lane sunk several shafts in the bottom of the tunnel, finding at a depth of 13 feet a bed of quartz gravel three feet thick, containing \$2 per ton in gold. This, if properly opened, would pay very well to crush in a mill but there is evidently much richer gravel than that in the hill, as it is a well known fact that all the ravines breaking out of the hill have paid enormously during early days and have since been worked over and over many times, a great deal of gold being taken out. There can be no question but that the rich deposits in the ravines and flats making out of this hill were fed from it. Drifting on the gravel beds either way might soon develop richer gravel than has yet been found.

SAILOR JACK.—The centrifugal roller mill at the Sailor Jack mine was put in operation on the 21st of May and has been grinding 12 hours a day since that time. County Clerk Bosquit informs us that everything is working nicely and that the mill is a great success on the soft rock now being taken from the mine. A Woodbury concentrator is also in operation and has saved about a ton of sulphurets from the ore. Ten tons of quartz are being crushed every 12 hours.

KELSEY.—*Georgetown Gazette*, June 4: Kelsey mining interests are growing right along. The St. Lawrence will soon be connected with the electric dynamo which supplies power to the Dalmatia mine and worked on an extensive scale. The Lady Livingston mine has been started up.

Inyo.

HIRSH MINE.—*Inyo Index*, June 3: This property that for a number of years laid idle is now, under the new working, fast developing into a veritable bonanza. Returns have been received from a carload of ore recently shipped showing that the 10 tons worked \$1,347.99. The assay gives 73% per cent lead, 66.4 to ozs. silver and \$70 gold per ton. A second carload was shipped yesterday. The lode now shows 18 inches of solid lead. When work was resumed on the mine, about three months ago, the gold ore was on the foot-wall and the lead ore on the hanging wall. These conditions are now reversed, and both ores have increased in quantity and quality. Five tons of the gold ore will be worked in the local Maxim mill.

Nevada.

THE HARMONY.—*Transcript*, June 6: For about a month past each tenth load of gravel coming from the Harmony has been put aside with a view to practically determining as to whether the bulk of the gold in the dirt was being saved by the washing process alone. A large quantity of the gravel thus saved has been crushed at J. C. Locklin's mill and it yielded \$6.07 a ton, whereas only about two dollars a ton has been realized from washing alone. There are now several thousand tons of tailings at the mine, and it is believed that with a mill on the property the tailings can be crushed at a cost of not more

than 40 cents a ton. The gravel is of quartz formation, hence the necessity for crushing it. It is anticipated that the Co. will be out of debt by the end of this month. The stockholders are happy, which is quite natural under all the circumstances.

CALIFORNIA MINE.—*Grass Valley Union*, June 6: The developments making in the California mine are quite encouraging, as the quartz coming from both the north and south drifts on the bottom level (180 feet) is of good milling quality showing well in free gold and sulphurets. The ledge is somewhat broken up in the shaft and drifts, but it is evident it will be found regular and of good size by deeper sinking. Crushings will be made of the quartz from the lower drifts as soon as sufficient is taken out to make a good milling test.

THE MINNIE CO. WINS.—*Grass Valley Union*, June 4: The jury in the case of the Minnie Mining Co. vs. Tilley et al, which was on trial in Superior Court since the early part of last week, returned a verdict on Tuesday night in favor of plaintiff. The ground in contest, is situated on Cabin Flat, to the west of Gold Hill, in this district, and embraces about six acres of mining ground. The suit was brought to quiet title, as the defendants had made application for U. S. patent to the ground in dispute. The case is likely to be appealed to the Supreme Court.

THE NEW REDUCTION WORKS.—*Grass Valley Tidings*, June 4: The first "charge" was put through the Grass Valley reduction works at Union Hill this morning. It consisted of tailings and was put through merely to fill the interstices here and there in portions of the plant and to test the bearings, etc. The works will start up "for good" next Monday, and Manager Higginbottom informs us that he is assured there will be no lack of material to work upon. Seven tons of ore, concentrates, and sulphurets have been received for sampling purposes within the last few days.

GRAVEL MINING ON A SMALL SCALE.—*Grass Valley Tidings*, June 4: Down in Rough and Ready township a number of gravel miners are making big wages by the drifting process, working singly in some cases and by twos or threes in others. Two or three Portuguese are in particular doing well, although their knowledge of mining is evidently limited. One cut a gravel channel in a side hill lately, but instead of running a tunnel in on the channel and working the deposit systematically, he merely makes a cut into the hill, drifts out about 10 or 15 feet of the channel, and then repeats the operations. Notwithstanding the immense amount of dead work done, however, he makes it pay.

NEW SHAFT ALMOST COMPLETED.—The new 3-compartment shaft on the Peabody is down over 235 feet, and with 25 feet additional depth will cut the lowest level of the old workings. The shaft is a very large one and most substantially timbered. When the work of development is again fairly under way the Peabody will be frequently heard from, as the outlook in the old workings is all that a miner could desire. With a mill on the ground the Peabody will pay dividends right along.

A MILL CERTAIN.—We are informed by a member of the St. John M. Co. that arrangements for a 10-stamp mill to be placed on the property have passed the stage of negotiation and are all but consummated. The mill will be in operation before the snow flies. Of late, work in the mine has been confined to straightening the shaft and driving the west drift, in which the ledge continues to average five feet in width and the ore to improve.

RICH QUARTZ FROM THE CALIFORNIA.—Some very handsome and rich quartz was brought in from the California mine at Deadman's Flat on Tuesday. The ore came from the face of the north drift, which is now in about 20 feet from the shaft, and shows coarse gold freely. A small leaf of gold is also to be seen. The vein at this point is four inches wide and enlarging steadily. In view of the location of the mine we would not be surprised if a bunch of specimens is unearthed. In the south drift the ledge is a foot wide, the ore full of mineral and evidently of a good milling grade.

Plumas.

A BULLION PRODUCER.—*Oroville New Era*, June 3: Among the arrivals yesterday were Messrs. J. H. Frissel and A. J. Greeley, from La Porte. Both gentlemen are connected with the Union Consolidated mine, the former as a one-fourth owner, and superintendent. Another fourth is owned by W. S. Chapman, of S. F., and the remaining half by an English syndicate. The claim is located about five miles east of La Porte and is worked by drifting. About 100 men are on the pay roll, and the monthly expenses average in the vicinity of \$10,000. This large expense is met, however, by a monthly bullion output of about \$20,000.

SAVERCOOL.—*Greenville Bulletin*, June 3: Several days ago, Mr. Reed, of the Savercool mine, was up from below to inspect that property. It is rumored that steps will be taken immediately to put the mill in operation. However, considerable will be required to do this, as a plant for either steam, water or electrical power must be put in.

San Diego.

AN IMPORTANT SILVER STRIKE.—*Julian Sentinel*, June 4: No doubt it has been noticed that no mention of the new strike, of which the San Diego dailies made mention some time since, has not before appeared in these columns. The reason for this silence is easily explained. News of this nature should be given with a great deal of caution, and up to the present time there has been no definite information obtainable. The *Sentinel* is now in possession of information which is deemed reliable, having obtained it direct from the discoverer, Mr. Dan Higgins, more commonly called among the miners "Lucky Dan," from the remarkable luck that has followed his efforts in times past. Lucky Dan is an old silver prospector, and has discovered and sold mines enough, had he but taken care of his wealth, to have been numbered among the millionaires of the day. The new camp lies southeast of Julian some 50 miles, and is near the Dos Cabezas springs. A new district is to be formed and will be called the Higgins district. The formation is limestone and porphyry, and the belt extends from Mexican line some 30 miles northwest, and lies east and almost, if not quite, parallel with the gold belt. Its importance to the country cannot be estimated at this writing. A. J. Burnett, former owner of the High Peak mine in Julian, is associated with Mr. Higgins in the nine locations already made in the new camp, and we are indebted to him for the re-

sult of the assays made by W. S. Young, of San Diego, last week which are here given: Virginia per ton \$271.00; Charleston, \$278.32; Washington, \$68.88; Silver Hill, \$98.48; Silver Peak, \$74.00; San Diego, \$83.33; California, \$36.73. Quite a number of prospectors left Monday and Tuesday for the new field by way of Carrisero creek, that being deemed the nearest and best route. They are prepared to investigate and test the rock on the ground.

Siskiyou.

QUARTZ.—*Yreka Journal*, June 3: Active mining operations are carried on at the Schroeder & Werner quartz mines on the head of Deadwood creek south of Yreka with good success. The mill is kept running steadily day and night, and a large force of men are employed in both mill and mines, to supply the necessary force of day and night shifts. In addition to taking out a large amount of paying quartz, the other ledges owned by this company are being well prospected this season. A company has commenced work on a blue gravel claim about three miles this side of the Klamath river, near Ager, at the Richardson boys' old place, and find very rich prospects. This company is known as the Sacramento M. Co., and comprises G. A. Barr, formerly of the Black Jack, Calderwood and son, Gerber, Avery, and Pierson, of Sacramento.

GRAVEL.—Lee, Lab & Co. were obliged to suspend work last week, on account of the breakage of their wheel, but expect a new one from below this week to resume work again. They struck some very rich blue gravel when the breakage occurred, and will have a good supply of water for washing, provided parties on the creek above them do not use it all for irrigating purposes. The Yreka Blue Gravel Mining Co. will receive stock books in a few days to issue stock and commence work by sinking a shaft. The place for sinking has been selected somewhere near the divide at the Oberlin road crossing from Yreka creek to Shasta valley. Should good prospects be found, there will be a grand mining boom in Yreka basin, which is destined to make times lively in this city. Experienced miners who have been investigating this section, feel confident that rich diggings will certainly be found, and that an extensive ancient channel will be found running through Yreka basin down to the Klamath river. Considerable quartz is being taken out from the quartz mill at Long Gulch, a couple of miles north of Yreka, and the mill at that place under the management of H. B. Green, is kept busily engaged in crushing. Boyle & Co. are putting up a new stamp mill at the head of Humburg creek, to take the place of their grinding mill, which did not give good satisfaction. Old quartz miners think there is nothing equal to a good stamp mill. Dave McCook, of the mill at forks of Humburg, is assisting Boyle in superintending the work of putting up the new mill. Hegler & Aldrich, of Humburg creek, have struck a very rich body of ore in their mine and are now running their mill constantly in crushing the quartz taken out, expecting to realize a large amount of gold this summer.

The McConnell & Quinn mine at Klamath river is now being open for summer work under the management of A. Smith, an experienced river miner. He keeps a force of men working day and night, excepting Sunday nights, and is doing as well at night as in daytime by using their electric lamps which work well in supplying plenty of light. It will not be long before the bedrock in the channel is reached, when they will begin to take out pay gravel for sluicing.

Ventura.

OIL REGIONS.—*Ventura Free Press*, June 5: The development of the oil region is yet in its infancy in this county, and although the output is estimated at 30,000 barrels a month, it is safe to say that the supply will far exceed that amount in a year or two more. It means millions of dollars in wealth to this county. In the county clerk's office to-day, articles of incorporation of two new oil companies were filed, one called the Far West Oil Co., and the other the Rainbow Oil Co. Each one capitalized at \$50,000 and the incorporators are Lyman Stewart, W. L. Hardison, John Irwin, Alex. Waldie and T. R. Bard. The place of business is at Santa Paula.

NEVADA

Washoe District.

JUSTICE.—*Virginia Enterprise*, May 6: Shipped 147 tons of ore to the Washoe mill, worth \$22.50 a ton, as per battery assays.

SIERRA NEVADA.—630 level: West crosscut No. 1 from the northwest drift has been advanced 90 feet; total distance, 447 feet. There is no change to report in the formation.

OCCIDENTAL.—Extracted pay ore from the 350, 400 and 450 levels. North drift from No. 1 upraise, 500 level is in 114 feet, face in low-grade quartz. The upraise from the end of the south drift, 600 level, is up 30 feet; the top is in fair ore. The north drift from No. 2 winze, 650 level, has been connected with the south drift run from the bottom of No. 3 winze, and the circulation of air on that level is much improved. The south drift from No. 1 winze, 750 level, is in 108 feet; face in low-grade ore.

SCORPION.—The joint north drift from the 900 level of the Union shaft was advanced 26 feet, making its total distance 93 feet from the shaft. The face is in porphyry and clay.

ANDES.—East crosscut, 420 level, advanced 20 feet during the week; formation, clay and quartz. East crosscut from the south drift, 420 level, has been advanced to feet; formation, hard porphyry. The main south drift has been advanced 6 feet; face in vein porphyry.

BEST.—Have 55 tons of rich ore at the mill. The mine is opening out rich in an entirely new spot.

ALTA.—Are running the mill on tailings, of which there is a large quantity on hand.

YELLOW JACKET.—Shipping 40 tons daily of silver ore to the Santiago mill, worth about \$18 a ton, and 100 tons daily of gold ore to the Brunswick mill which is low grade.

OVERMAN.—Shipping on the average 100 tons daily to the Brunswick mill, ore worth about \$15 a ton. Are preparing to do important prospecting work in the mine.

SEG. BELCHER.—On the 600 level the west crosscut from the south lateral drift is 83 feet. It is still in soft porphyry.

CHALLENGE CON.—The joint Confidence and Challenge west crosscut on the 600 level is out 60 feet, 12 feet having been made during the week; the face shows quartz of no value. Joint Confidence and Challenge north drift on the 1100 level is in 293

feet, 20 feet having been made during the week; the face being in porphyry.

CROWN POINT.—The east crosscut from the south end of the 350 stope on the eighth floor has been advanced 26 feet during the week and is now out 58 feet. The face is in a mixture of porphyry and clay. The east crosscut on the 1000 level has been extended 26 feet since last report, and is now out a total distance of 156 feet. The face is in vein material composed of clay and quartz.

BELCHER.—The south drift from No. 2 crosscut on 200 level has been connected with No. 1 east crosscut. The north drift on 300 level is in a mixture of low-grade quartz and porphyry. The 1500 level east crosscut is in quartz assaying from \$75 to \$75 per ton.

CON. IMPERIAL.—We are still following up and taking out small streaks of ore on the upper levels and prospecting in and around the old stopes, where we find some fillings and hunches of ore of fair grade, which is being shipped to the Brunswick mill for reduction.

SAVAGE.—Milled 440 tons of ore of the average battery assay of \$17.53. We have haulion on hand amounting to \$27,767.60. The E-street tunnel has been repaired and advanced 60 feet since last report, making a total distance of 650 feet. On the 1400 level the east crosscut is in quartz and porphyry. Have started an east winze in north drift in quartz and porphyry. The west drift from the station on the Potosi level was advanced 24 feet; total, 73 feet. On the 750 level we are extracting rich ore.

HALE & NORCROSS.—On the 1400 level the winze from No. 3 east crosscut is down 135 feet, the bottom in porphyry. The joint winze in No. 5 east crosscut on our south boundary is down 25 feet. The bottom is in porphyry. On the 1500 level the north lateral drifts from the station was advanced 40 feet; total 50 feet. The face is in porphyry. The south lateral drift from the station was advanced 30 feet; total, 40 feet. Face in porphyry. Are constructing a double chute at the station on this level.

UTAH.—Incline winze has been sunk 35 feet; total depth, 130 feet, continuing in porphyry, clay and quartz of low assay value.

NEW YORK.—North lateral drift, 600 level, is in north of shaft 232 feet; face in porphyry. North lateral drift, 1100 level, is in 521 feet; face mostly in quartz yielding low assays.

SILVER HILL.—The southwest drift, 50 level, is out from shaft 80 feet; face in porphyry. South crosscut, 160 level, is out from winze 565 feet; face in hard porphyry.

CHOLLAR.—The south drift, 1400 level, from the north line, is out 137 feet; face in porphyry. The winze in the joint east crosscut, north line, 1400 level, is down 32 feet; the bottom is in porphyry. Extracted and sent to the mill the past week 524 tons of ore, the average battery assay of which was \$23.36 a ton.

POTOSI.—The winze is down 132 feet below the 1400 level; the bottom shows porphyry and streaks of quartz. The south lateral drift from the Chollar incline, 1100 level, is out 218 feet; face in porphyry.

WARD COMBINATION SHAFT.—The south drift from the 1800 station is out 60 feet; face in clay and porphyry.

EXCHEQUER.—The east crosscut on the north line, 600 level, is out 228 feet, face in clay and porphyry.

BULLION.—South lateral drift from the Potosi, 1300 level, is out 80 feet; face in clay and porphyry.

ALPHA.—West crosscut, 100 feet north of the shaft, is out 564 feet; face in hard porphyry.

UNION CON.—West drift from the shaft, 900 level, has been advanced 55 feet; total distance from shaft, 319 feet; face in clay and porphyry.

Cortez District.

PROSPECTING.—Battle Mountain Nevada, June 4: S. J. Jolin and Jack Houston have returned from a prospecting trip to Cortez district. They have prospected the mineral belt and find it to be about eight miles square, the center of the lode being Cortez. Outside these lines the country contains hardly a trace of good ledge formation. The examination of the district, lasting 20 days, has made a good impression on Sam Jolin, but the section is completely covered with claims. He purchased the Badger mine in Mill canyon, five miles north of the town and says there is ore enough in the croppings to more than cover the purchase price. A quarter of a mile above the Badger are the claims located by the Norrie diving rod, that at present a new departure in prospecting. Inside the stakes there are no signs of ore, but the rod indicates a large vein and on its merits the locators have recorded and purpose doing development work. In this canyon the Wenban mill stood before the change. Some of the claimants in the canyon are Ben Carter, a man named Texas, Gilham Bros., John Erving and Geo. Engstrom. The Badger contains a vein from one to three feet wide, carrying \$46 to \$342 in silver. As it is only 30 miles to the Central Pacific, over a level road, the property is a promising one. On their way in the parties made the drive to Galena in a day. They departed Tuesday to begin operations and the extraction of ore for shipment to Selby & Co., San Francisco.

Eureka District.

SMELTERS STARTED.—*Eureka Sentinel*, June 6: The Eureka Con. Co. started up their smelters last Wednesday. This will give employment to quite a number of idle men who have been patiently waiting for this event to occur.

Revelille District.

SATISFACTORY.—*Belmont Courier*, June 3: Arthur Delano recently hauled a load of silver ore from Revelille district, Nye county, to the Eureka reduction works, and we learn from Mr. Engbough that the result of the crushing proved very satisfactory to Mr. Delano. The net profits amounted to \$800. This shows that rich ore exists in that section of Nye county.

Rattlesnake District.

SILVER.—*Belmont Courier*, June 3: Charles Kanrohat is at present developing his silver mine in Rattlesnake district in Eastern Nye county. Joseph Engbough informs us that there is rich ore in sight, and he believes that Mr. Kanrohat will extract considerable good ore from this mine during the summer.

Indian Creek District.

PLACERS.—*Silver State*, June 4: Mr. J. B. Foltz, who is extensively interested in placer mining in Indian Creek District, came in yesterday, and after attending to some business in town, left for Verdi and Sacramento, to finish the purchase of

lumber and other supplies necessary for his camp. He stated that he had about half the material on the ground at present, and that he has ten men at work, in clearing the way, constructing and putting up the flumes which are to carry the water some two miles. Owing to the stormy weather he had been somewhat delayed, but he expected to be taking out dust now in a very short time.

Hawthorne District.

LAPANTA.—Walker Lake Bulletin, June 3: During the week the incline below the tunnel has been continued, showing a strong vein of high grade ore. The south drift from the incline has been extracted 16 feet showing the same character of ore all the way. An incline has been started from the northwest crosscut from the main tunnel, and is down 15 feet, the entire incline being in a body of iron assaying $7\frac{1}{2}$ gold, 20 ounces silver, with the exception of 10 inches on hanging wall which is $\frac{1}{2}$ gold ore. Stopping above main tunnel still continues, and a raise has been started above the north drift, 100-foot level of the shaft, showing 18 inches of $\frac{1}{2}$ gold ore.

PAMICO.—The lessees still continue to extract good ore from the stope above the north tunnel, the incline below the location tunnel, and the stope north of the long incline, and a new vein of very rich ore has been discovered on the surface between the location tunnel and the north tunnel.

CENTRAL.—Principal work this week has been sinking incline and stoping above 75-foot level. Two car-loads of gold ore shipped this week.

MOUNTAIN KING.—Main tunnel still being run ahead to cut the hanging wall vein.

HARTFORD.—An incline has been started on the vein near the location point, ledge about eight inches wide, half lead ore and half $\frac{1}{2}$ gold ore.

BEACON.—Stoping each way from the incline still continues.

CAPITAL.—Still drifting on the vein.

GOLD BAR.—Still drifting north from the bottom of the incline winze showing very well.

DICTATOR.—Still engaged in opening vein on the surface. Same is showing extremely well.

CONFIDENCE.—The ledge on the incline from northwest drift running flat, and has been followed 15 feet during the week. Same has now been stopped and prospecting is being done from the vein in the canyon west of the old works. Forty-five tons of ore being shipped this week.

FAIRMOUNT.—The main south drift has been extracted 16 feet, the total length of the drift being 100 feet on the vein. The last 50 feet having ore all the way. The grade of the ore has improved considerably during the week. Considerable 400 ounce ore is being extracted.

CHALLENGE.—Winze below tunnel is now down 16 feet. An eight inch vein on the foot-wall, a six inch vein on the hanging wall; the average value of the vein being about 60 ounces, with occasional bunches of 500 ounce ore in same. The main drift is being run ahead, showing a five inch vein in the face carrying some ore.

Tuscarora District.

NEVADA QUEEN.—Times-Review, June 5: South drift from Commonwealth 4th level has been advanced 12 feet in vein formation giving low assays.

DEL MONTE.—Joint west crosscut, 3d level, has been extended 25 feet; have a large amount of water. Joint raise from crosscut up 13 feet.

NAVAJO.—The stopes on the 350-foot level continue to produce their usual quantity of ore. The water has been materially increased by the prolonged heavy rains.

NORTH COMMONWEALTH.—Ore produced from stopes, 32 carloads first-class, assay, $\$20$ per ton; 62 carloads second-class.

COMMONWEALTH.—Stopes have produced 56 carloads of ore, assay $\$45$ per ton; total out, 130 carloads. 4th level: North drift from east crosscut advanced in the vein 12 feet; seam in the face of high-grade ore, picked sample assayed $\$98$ per ton. Crosscut in from north drift in 12 feet, average assays of three feet $\$14$ per ton. In raise from east crosscut have three seams of high-grade ore; assays show high percentage of gold.

BELLE ISLE.—North drift on the ore recently cut in the west crosscut from the 350-foot level is 18 feet; the face is showing a large vein of rich ore, full of ruby. South drift, same place, is in 23 feet; the vein continues strong and high grade; producing 11 cars of first-class and 28 cars of second-class ore. In both drifts the showing is very fine, the ore is clean and solid and has the proper pitch, with every indication of permanence.

NORTH BELLE ISLE.—North drift from Belle Isle 450-foot level extended 7 feet and crosscut started east 12 feet; rock very hard. No. 1 winze from same level extended 12 feet and suspended. No. 2 east crosscut from 400-foot level extended 18 feet; stringers of good ore are beginning to show in the face. The stopes above this level continue producing 95 cars of second and 6 cars of first-class ore. Have started crosscuts from the 600 station to cut the vein east and west of it.

ARIZONA.

COPPER.—Journal Miner, June 4: The United Verde Co. is turning out about two car loads of copper bullion and matte daily. It is being shipped to New Jersey to be refined. Over 70 car loads of ore and bullion have been shipped out this month over the Prescott & Arizona Central railroad. This goes to show that mining operations here are by no means on the wane.

SMEILER.—The Commercial Mining Co.'s Big Bug smelter has been started up, and a car load of bullion was shipped from there yesterday. Shipments are made by wagon to Verde Station on the Prescott & Arizona Central railroad and thence by rail.

KEYSTONE.—Charles Wallace is cleaning out and retrimbering the old shaft of the Keyhole mine, seven miles south of town in the Hassayampa district. This claim is one of the oldest in this section of the country, having been located in 1865 as the Benedict mine. A shaft was sunk to the depth of 66 feet on the claim, and remarkably rich ore was taken from it, some of which paid a profit for shipment even in those days of wagon freighting for hundreds of miles, the freight on a ton of ore, amounting to a small fortune in itself. Notwithstanding the richness of the ore, however, it would not bear shipment at a profit except as the ore was sorted out very carefully, and the claim was abandoned and remained idle until about three years ago when it was relocated, as the Keyhole

mine. Mr. Wallace coming into possession of it has placed men at work putting it in shape to be worked, and he is confident that he has a bonanza in it. His confidence is not a blind one by any means either, but is based on the former history of the property together with results obtained by exploring the ledge. Since commencing work he has had a shaft sunk 18 feet deep on the north end of the claim and has taken out galena ore, bearing silver which gives an assay value of $\$1,500$ per ton. As soon as the old shaft can be cleaned out and retrimbered he will commence taking out ore from it. The ledge can be traced distinctly for a mile on the surface of the ground.

SWISSHELM.—Tomahstone Prospector, June 5: C. F. Hine is in from the Swisshelm mountains and is feeling jubilant over the looks of the Swisshelm properties being worked by him. The main ledge has been struck and shows a strong four-foot of carbonate ore which will average 60 per cent lead, 50 ozs. silver and $\$20$ in gold. He says it is the biggest thing ever struck in Cochise county. He has two carloads out ready for shipment. But four men are at work upon the mine at present, and the ore taken out is simply what is necessary in development work. Charles is always over sanguine, but parties who have seen the property corroborate his account of it.

LEASED.—B. S. Coffman has leased a portion of the Bunker Hill property to George Goldworthy and others. He will also put a few men at development work. This departure from the custom of shutting down a property rather than lease it is a new one in Tombstone, and the result will be watched with interest. Mr. Coffman gives the chlorides the use of the hoisting works. The Comet makes regular shipments of manganese ore. The dry concentrating works at Bowie, it is said, are not successful, and other works will be put in.

COLORADO.

GOLD.—Denver Tribune-Republican, June 4: Probably the richest ore ever found in Colorado is that disclosed by the recent strike in the Cabinet-maker and Stenographer on White House mountain near Ouray in the San Juan. Unfortunately there is but a small narrow streak of it and it would take a long time to get a ton. Pieces of the ore have assayed as high as $\$200,000$ per ton in gold, and a small mill run of the rich pay streak gave $\$120,000$ per ton. It is a gold quartz and parts of it are so filled with free gold that a polished specimen on its face seems to indicate that the rock is at least 50 per cent of the precious metal. The mineral occurs in a fissure vein. Parallel with the gold streak is one of silver telluride, which carries 700 ounces of silver and three of gold, and the entire vein between walls gives a mill run of 13 ounces of gold and 25 of silver. The property is held under bond and lease by H. G. Sayles of Denver and Mark Atkins of Ouray. A syndicate of Denver capitalists was formed yesterday to buy a six-eighths interest in the property. It contains a number of leading real estate and mining men of the city, but their names will not yet be made public, nor will the price paid.

IDAHO.

STORMY HILL.—Idaho Avalanche, June 3: Drifting south from the shaft and putting in stulls for stoping, is being pushed on the Stormy Hill mine. A large amount of good ore is out ready for hauling to the mill as soon as the roads are repaired, which, we understand, will be done this week. The Black Jack mill will start up again, the pulp tanks having been reconstructed. Gravity tanks were placed in the mill when it was built, but owing to the character of the ore, had to be taken out and replaced by ones of different construction. The Flint mill will shut down Monday for the purpose of adding new machinery for increase of capacity. This will require four or five weeks' time, after which a force of miners will be put in the Rising Star mine belonging to the company. This mine has over 50,000 tons of good milling ore ready for stoping, with good ore in the face of every drift. The Poorman Co. increased its force of miners during the week, and it now looks as though the owners meant business. It is well known by every man who has been through this property that the mine is in shape to produce a large amount of good ore whenever the owners so willed. The old New York mill property has been attacked by a kind of decay which has within a short time left the old Chariot and Minnesota hoisting works nothing but holes in the ground. One by one the buildings around the old mill are tumbling down, and the lumber suddenly disappears. This property cost nearly $\$300,000$, but for 15 years it has belonged to a defunct corporation of which some stockholders still exist. There is no watch on the property and no sympathy for its owners wasted here; but the "decay" of the buildings is grand larceny all the same.

OREGON.

NEW SMELTER FOR MINERAL.—Bedrock Democrat, June 3: Messrs. George A. Fitch, of Tacoma, and C. C. Wing, owner of the Sommer & Wing mining property of Mineral City, are in town on their way to Portland for the purpose of purchasing machinery for the proposed new smelter to be erected and in operation at Mineral within the next sixty days. In case the necessary machinery cannot be purchased in Portland they will proceed on to San Francisco. We understand the mines of Mineral are developing into wonderful properties and it has become necessary to enlarge the present facilities for the reduction of the ores. The Porphyry Smelting Co. will, however, continue to operate and be supplied with all the ores its capacity will accommodate.

ARRASTRA.—Jacksonville Times, May 29: Provolet Bros. are preparing to put in an arrastra soon at their ledge in Murphy precinct. Selph & Taylor's arrastra is running at the March & Selph quartz ledge in Sam's valley, on excellent ore. The Patton mine near Talent has been running out some very promising ore lately, which has been hauled to Anderson's mill for reduction. Miners on Applegate are encouraged in their search for the precious metals by the sound of two steam whistles, one of them belonging to Bailey's steam arrastra, the other to Flannagan's quartz mill. Harry Lewis and Dr. Kremer of Grant's Pass have bought out Schrimp Bros.' interest in the North Star mine in Josephine

county, and will at once proceed to develop the property to the fullest capacity. Simon Messenger of Josephine county is succeeding nicely with his arrastra this season, but will put in a Huntington mill this fall in order to be able to handle the entire output of his mine with the least loss. The tested rock from the ledge located last week by Messrs. McCall and Porter, near Gold Hill, promises exceedingly well, and as the ledge seems to be almost without limit, big things may be looked for from that neighborhood. Mr. Porter has had many years' experience in mining in the Idaho diggings, and is of the opinion that the main ledge, of which the pockets heretofore discovered in the vicinity of Gold Hill are but spurs, has at last been found. The ore does not show anything fabulously rich, but the rock carries a great deal of gold.

LOWER CALIFORNIA.

MEXICAN GULCH.—Lower Californian, May 28: Mr. A. M. Kickert came in from Alamo last Monday on a business trip. He has been living in Mexican gulch, five miles this side of Alamo, for the past five or six months engaged in placering. In a conversation regarding the gulch, he said that the impression among mining men here and at Alamo that the placers in the gulch had been worked out was a great mistake. "I have been in the Alamo district ever since the excitement two years ago," said he, "and have done better in Mexican gulch than anywhere else in the vicinity. The placers there had been abandoned before they had been thoroughly worked, and for a long time the place was entirely deserted, but since my partner and I went in there a few months ago and got down to work there have been others follow our example, until there are at least a dozen men in the placers. All of them are doing well, apparently, though of course hard work is necessary in ground that has been gone over once. In a claim that was deserted by its former owner, and which we denounced about 10 days ago, we have already taken out three nuggets weighing 17, 46 and 45 pennyweights respectively, besides a fair quantity of finer gold. In my opinion Mexican gulch is not yet worked out. Regarding the Alamo mines, it seems to me that they are all right. Although the Indio has been shut down, the San David, near by, is said to be in good ore, and several of the other mines are prosperous. I look for a big strike to be made in the Alamo district some of these days, for it is plain that the mother lode has not been found yet. Where there is so much surface gold there must certainly be a big deposit near, and when it is found the camp will boom in earnest.

COPPER MINES.—Three hundred peons have been secured in Colima to work in the copper mines of the Boleo Co. in Lower California. For experienced miners the company offered from $\$1.25$ to $\$2$ per diem, and to men without knowledge of mining $\$1$ to a trifle more. In addition, the men with their families were given free transportation to the mines and were promised free houses there. Colima papers seem to anticipate that the men are not strong enough for the work.

MONTANA.

CASTLE DISTRICT.—Cor. Mining Journal, June 3: The Armada Co. has purchased and has enroute from Livingston a steam hoist which will be set up on the Armada lead. The company besides owning the Armada, which lies north of the Yellowstone, also owns the Smuggler, the Little V, located between the Yellowstone and Great Eastern, and the Sleeper, which joins the Cumberland on the east. The Hidden Hand Co. has let a contract to sink a new shaft 100 feet on the Dunderberg. In the old shaft a body of iron was encountered; the new shaft will be sunk further up the hill, and will be sunk to catch the same lead. On the road from Castle to Robinson there are several promising prospects, among which are the Gem, owned by Peters, Kertz, Phillips and Shaffer, upon which a 40-foot shaft has been sunk in a fine body of iron ore suitable for fluxing. The famous Hidden Treasure is next met. The shaft is 187 feet in depth. They have been hoisting with a whim, but as it was slow work the company concluded to put on a hoist. The company has let a contract to run a crosscut at the 100-foot level fifty feet, more or less, until the lead is struck at the bottom of the shaft, when connections between the two drifts will be made for air.

A STRIKE.—Montana Mining Journal, June 3: It is reported upon authority that a very rich strike of galena carrying sulphurets was made this week in one of C. Vaughan's locations in the Vaughan district, near the Peerless Jennie. An experienced miner who had seen the strike, remarked that Vaughan would yet wear as large diamonds as the Peerless Jennie people; it is to be hoped that he will be patriotic and wear Montana gems.

BARKER.—The grade to Barker from Monarch is quite completed and track laying will be commenced early in the month, and July 4th may mark the date when Barker's commercial isolation shall end.

BELL BOY.—Another car of ore is on the way from the Bell Boy, in Tousey Gulch, above Marysville. Shipments from this mine are occurring with pleasing regularity, and the net returns are as fully satisfactory.

THE LION.—The Lion Co. has purchased and will have in operation this week, on the mine in Deer Lodge Co., air compressors to work the drills. Work on the 300-foot level in the south vein has drained the 200-foot level of the north, proving some connection between the two veins, possibly a union.

PLACER MINING.—Another copious rain keeps alive the joy in the hearts of the placer miners. From all points come reports of work being pushed to the utmost capacity, day and night work being carried on wherever there is sufficient water. Montana will certainly not be behind any State in the production of placer gold this season.

NEW MEXICO.

DIFFERENT DISTRICTS.—Pinos Altos, June 5: Pete Wagner started up his mill yesterday afternoon on ore from John McDonald's mine. Bell & Stephens' mill has closed down for a few days. This was rendered necessary on account of lack of teams to haul ore. A gentleman in from Carlisle informed the Pinos Altos that that camp is almost deserted, though a few claims are being worked. James Tong, Mr. Cook and I. Goldsmith are taking out

ore from the Alhambra mine, formerly the Jumbo, at Carlisle, which runs away up in the hundreds. The contractors are at work putting in the framework for the stamps in the Mammoth mill and will put in the irons as soon as they arrive, which are expected every day. J. Kindell and J. D. Lee report Cooney, although not being on any particular boom at present, a good steady camp, and have undoubted confidence in its future greatness. On the Kleptomania they are drifting both ways on the 350-foot level. A rich body of ore was encountered at the end of the crosscut in the drift, a test run of which is now being made at the Aztec mill. At present there are 25 men at work on this mine. N. H. McCustian is taking out a goodly amount of ore from the Geronimo mine at Carlisle which runs over $\$500$ to the ton, and had a carload ready for shipment last week. The Birthday mine, the happy possessor of which is Mr. J. N. Whitaker, has a 6-inch vein which runs over $\$17$ per ton in gold on the plates. The shaft is down 50 feet and the ore body is widening out as depth is attained. There are three men at work on the Ribbon mine, owned by H. M. Stanley, hoisting out water preparatory to sinking. The Ribbon adjoins the Mountain View, and in the past some very rich ore has been taken out of it. Pacific No. 1, is working 40 men and taking out a ton of ore to a man per day. This mine never looked better than at this writing. Supt. John Spiller says the Pacific mill is at present dropping 15 stamps, but would, he thought, in a short time be running at its full capacity of 30 stamps. The mill is, with 15 stamps, putting through about 35 tons every 24 hours. The Harvey Bros. and Holman are working on their Homestake mine. The shaft is down between 40 and 50 feet with a 12-inch pay streak. Tuesday they struck a body of ore which for beauty, variety of metals and indicated richness is second to none in this section. It is full of native copper, as well as silver, and carries sulphide of silver, gold, iron and lead.

SOUTH DAKOTA.

GRIZZLY GULCH.—Deadwood Pioneer, June 4: Some day Grizzly Gulch will develop a number of gold producing mines that will rival the Homestake and kindred properties. It has several quartz lodes of known value, and recently Joe Stahlcup discovered some rich placers yielding coarse gold as high as $\$9$ per ounce. He has 20 acres of placer ground in the gulch, and has frequently found spots which yielded 500 to the pan. Last week he worked three days on one of these patches and with only pick and shovel cleaned up $\$14.50$. Above these places are some good quartz mines that only require capital to open up and build mills. The gulch is only three and one-half miles from Deadwood.

RICHMOND.—Deadwood Pioneer, June 3: The Richmond mill was all ready to start up, when Supt. Havens determined not to start it up, but to put in a plant for oxidization similar to that described heretofore in the Pioneer, and one of which is now in course of construction at the Montana mill. The process is to roast the ores by means of petroleum, and then to oxidize the metals by the application of sprays of water. Mr. Havens is confident that the process will succeed, and if it does, it will materially decrease the price of working refractory ores.

SQUAW CREEK.—A party of Galena miners will leave to-morrow for the new silver camp on Squaw creek. A gentleman who recently came up from there says that the mineral is all found in the slate, and that the only discovery of any importance is that of Judd the original discoverer. He says that the discovery was made in a draw, and nobody but a farmer could have found it, as there were no outcroppings or signs of mineral anywhere.

WASHINGTON.

MORE KITTITAS GOLD.—Edinburgh Capital, June 4: Torkel Tweet came down from the Swauk last Monday, bringing with him the result of three days' work with a hand-mortal, in the shape of gold amalgam, weighing 59 ounces and valued at $\$960$. This strike was made near the Pike claim, and when found had the appearance of a fissure vein. It was panned out of decomposed quartz, a very limited supply of water being available. This latest product of the Swauk fields was greatly admired and it was generally conceded to be a remarkable production, and many were firmly convinced that the mother lode had at last been found. The piece was placed on exhibition in Rehmkne's window prior to shipment to the San Francisco Mint. Although this is a remarkable find for any country, it is doubtful whether it or the reports of it will attract the least attention until it gets to the Mint, where its value will be appreciated. It is very strange that after so many years of successful prospecting, so few men should be in the camp and so little interest should be manifested in it both in the State and outside. However, it will not take many strikes like this to open the eyes of the people to the fact that this is a gold-producing region.

THE PAULSON.—Ruby Miner, June 3: Another shift has been added to the force on the Paulson on Ruby hill, which is being operated on a working bond by Hansen & Dice of Spokane. The tunnel is now in 100 feet. These gentlemen express great satisfaction with the outlook and by the time the bond expires expect to have the mine looking like a good buy.

A NEW VEIN.—Bob Hargrove says that in running the tunnel to tap the Lake View ledge another vein has been encountered, upon which he is now running. The new ledge is six feet wide and carries good ore. He thinks it is the Hardscrabble lead.

FIRST THOUGHT.—In the First Thought mine a crew has been put to work sinking a winze from tunnel No. 2 to connect with No. 3. The contract to drive 700 feet on No. 3 should have been finished by June 1st, but hard rock and an excessive flow of water will delay its completion for probably 30 days. A portion of the regular force in the mine was detailed last week to thoroughly timber tunnel No. 4, preparatory to driving through to the 3000-foot station. Ore shipments continue regularly, the last wagon train taking out three tons of high-grade sorted ore.

RAINBOW.—The force heretofore working on the Coyote has been shifted to the Rainbow, both mines adjoining and being under the same management. The last-comer reports that the Rainbow tunnel is now running in first-class gold rock.

MECHANICAL PROGRESS

Forging by Electricity.

A New and Important Process.

A committee consisting of several gentlemen—prominent members of the Franklin Institute of Philadelphia—were recently invited to visit Boston for the purpose of witnessing a new and important application of electricity for forging iron. The reader will hear in mind that the welding of iron by electricity has already become a matter of very general and most successful practice; but the present writing is descriptive of forging iron by the same agency, and is quite new and equally important.

This forging plant is the property of the Electrical Forging Co., Boston. The exhibition to which we refer took place on the 13th ultimo. The plant consists of a 60-horse electric motor. The current, which is alternating may be used at a very low voltage, or increased up to 12,000 amperes. The heating apparatus consists of a number of clamps, with electrodes of peculiar design and construction which hold the metal to be heated; there are also numerous dies, presses, rolling machines, etc.

The Heating Apparatus

Is capable of giving a correct proportionate to the work in hand and is completely under control of the operator. The exhibition is described by the *Boston Journal of Commerce* as follows:

A bar of wrought iron inserted in the jaws of the machine was in a few seconds at a white heat, and finally melted, dropping to the floor a liquid mass. Another piece of steel was heated, one end fastened in a vise and twisted in close spirals throughout its entire length, at one heat. Other pieces, wound about a mandrel, formed a spiral spring at a single heat. A $\frac{3}{4}$ inch rod of steel was heated in a few seconds, heated into a knife blade, ground and inserted in a handle within a short time. A square bar of $\frac{3}{4}$ -inch iron was heated evenly throughout its length and worked into different shapes on the anvil and straightened again at a single heat. Many other interesting tests were made, all showing the rapidity with which the iron and steel can be heated by electricity and heated evenly within any limits desired.

The methods used being comparatively in the earliest stage of development, were necessarily crude, so that the exhibition was of value more particularly because of the possibilities it opened up. Forging of every description may be done, from that ordinarily given to the blacksmith, to work now done at the expenditure of considerable labor and time in specially prepared machines. Its capacity is limited only by the number of dies that can be made for the different articles it is intended to produce.

The Superiority of the Method

Lies in the evenness with which the whole mass is heated. The blacksmith now heats the outside of his metal to a white heat while the inside is comparatively cool. Under these conditions the outside rapidly gives off its heat and the work must again be placed in the forge to be reheated for further working. Then the metal is unevenly heated throughout, and when rolled or pressed into various shapes is entirely unreliable because of the unequal internal strains to which it is subjected by the unequal contraction of the article in cooling.

In the electric method the passage of slow alternating currents heats the interior of the iron first. This even temperature is particularly valuable in the tempering of fine tools and is absolutely necessary. It then becomes a matter of certainty instead of dependence upon the skill and judgment of a single man, probably, in a whole factory. The heating of the metal is so instantaneous that it is only in the path of the current and the projecting ends are barely warm.

It looked little short of marvelous to see a workman hammering a bar of iron a foot long held in his bare hands, while six inches of the other end was red hot. This merely indicates how readily any desired portion can be heated without affecting the rest, simply because it has not time to conduct the heat, and also showing how free the process is from all those disagreeable things that are inseparable from the present blacksmith's forge or rolling mill.

The freedom of the metal from all gases is another advantage, as it can be readily understood that when a piece is heated by a current of electricity no gases are developed; moreover, the metal, whether it be iron, steel, brass or composition, after having been heated by this process, is without scale, which is not possible under any other method. The question may suggest itself as to

The Difference Between This and the Method of Heating for Electric Welding.

They are essentially different. In the well known welding process the two pieces are brought end to end like the opposite poles of an arc lamp, the imperfect contact of the two pieces concentrating the current at the point of greatest resistance, and heating that point at once to the greatest extent. As the ends are pressed together new paths for the electricity are found until the whole of both ends are heated and forced together until welded. In the method for forging, however, the contact is as perfect as possible and heats the metal by the passage of the electricity through the metal to be heated. The process is the invention of George D. Barton of Boston.

Improved Armor Plates.

The efforts at improvement in armor plates for war vessels seems to be meeting with most unexpected success. The chief point heretofore sought for has been to avoid perforation by impact by increasing the resistance of the armor to penetration with very little thought in regard to the effect which such resistance might have upon the projectile.

An interesting test of armor has recently been made at Annapolis of plate manufactured upon quite a new system, and with special reference to the destruction of the projectile at the instant of impact. The system is founded on the homogeneous steel of Schneider, and adopting the admitted improvement of the nickel alloy, but using a new process of manufacture devised by Mr. H. A. Harvey of New York. The new system is described in the *Scientific American* as follows:

This process is that of decarbonizing the surface of the steel plate so as to give it a very high temper and extreme hardness, with a view to breaking up even the best projectiles. Taking a homogeneous plate of mild steel throughout, or of steel with nickel alloy, the front surface is treated by this process, with a gradual diminution of it in the interior, while the back of the plate remains untouched. The object is not continuing the hardening process throughout is to retain the toughness and tenacity of the mild steel at the back, so that if the projectile should break up the front, the tendency to crack all the way through will be avoided.

The Harvey plate in the present trials was manufactured by Carnegie, Phipps & Co. of Pittsburgh. In a preliminary test of the Harvey process, made last February, a plate 10 $\frac{1}{2}$ inches thick was fired at by a six-inch gun. Six rounds were fired, half with Holtz and half with Carpenter or Firming projectiles. The Harvey plate was very severely cracked by the end of the trial, but the naval authorities had grounds to believe that for a single shot a plate made under this process might resist better than any other ever manufactured. In fact, this armor had shattered two of the Carpenter shells, which had penetrated less than half way, and one of the Holtz, which did not get quite through. It was accordingly determined to try several other Harvey plates, to be made for experimental purposes by the Pittsburgh firm.

In order to test thoroughly, not only the intrinsic strength of the Harvey plate, but its relative efficiency, it was further determined to try no fewer than five plates, two of which should be of homogeneous steel, one of steel with a nickel alloy, and two of the nickel steel manufactured by the decarbonizing Harvey process, all made at the Pittsburgh works, and each eight feet long by six feet wide, but with a thickness of only three inches. This latter represents the protective decks and shields of some of our war vessels, and is sufficient for illustrating the comparative merits of the systems of manufacture. Of course, they could not be attacked by heavy guns, and a six-pounder Hotchkiss rapid-fire gun was substituted. The plates were arranged at a distance of about 12 yards from the gun, and 20 rounds were fired against each plate. The result was the complete destruction of the two steel plates and the penetration of the nickel steel as far as the oak hacking, which was entered and injured. But the Harvey plates kept out the projectiles from the oak hacking, and though they showed some cracks, they completely broke up the projectiles and gained a great triumph.

Taken together with the February test of a thicker Harvey plate, this trial makes it clear that still another advance has been made by our naval ordnance bureau in the method of manufacturing armor. It has also practically confirmed the conclusions reached last September, and in subsequent tests that an alloy of nickel yields better results than steel without the alloy.

A CIRCULAR SAW THAT PLANES.—Says a Glasgow, Scotland, journal of late date: "One of the simplest, although perhaps the most interesting exhibits in the mechanical section of the Glasgow Industrial Exhibition is a circular planing saw, exhibited by the Planing Saw Company, Limited, Nottingham, which cuts and planes all kinds of wood by the same action as an ordinary circular saw, producing a beautiful smooth surface, equal to hand planing, with little additional power and no more labor than is required for ordinary sawing. The invention is applicable to all kinds of circular sawing, and has already been adopted by some of the principal railway companies in their carriage and wagon hulling departments with the best results in the saving of labor and expense. There is no planing required, which should be invaluable to pattern-makers, cabinet-makers, packing-case makers, carriage and wagon builders, agricultural implement makers and all workers of wood generally."

BLOCKING SAWS.—Most mechanics who for the first time visit a shop where large circular saws are made, are much interested in the process known as "blocking" saws. This is the process by which they are straightened and the proper tension imparted to them, and is an operation requiring the exercise of exceptional skill and judgment as well as a great deal of experience.

IRON RUSTS more readily when subjected to alternations of hot and cold. When kept at about the temperature of boiling water it corrodes more rapidly than at any other degree of heat.

SCIENTIFIC PROGRESS.

The Mystery of the Ear.

"The human ear," said a scientist to a Washington *Star* reporter, "is an organ, the true inwardness of which the physicians have never been able to get at. They can examine the interior of the eye with ease by throwing into its dark chamber a ray of light reflected from a little mirror, and of late they have found it possible even to see the gray matter of the brain by looking through the little canal by which the optic nerve enters. The cavity behind the nose they inspect with the aid of a light placed far back in the mouth."

"They have no difficulty in seeing into the stomach by an electric apparatus; the intestines likewise are readily enough investigated and the bladder also. But the ear, as to its internal arrangements, is unapproachable. It is even impossible to dissect it satisfactorily after death, for the reason that the parts collapse at once when the vital spark leaves the body. The drum, in a living person, has the way to observation, and even though it be pierced, the winding passages beyond can not be seen through. On the other side of the drum are the three little bones—the mallet, the anvil and the stirrup—which act upon each other as levers. The drum acts as a sort of buffer, and the mallet, immediately in contact with it, conveys the sound waves through the anvil and the stirrup to the 'cochlea,' a spiral, shell-shaped chamber just behind and above the external opening of the ear."

"This shell is composed of filaments of the auditory nerve, coiled spirally, and each one erect and waving tremulously in response to the slightest waves of sound. They carry the sound impressions directly to the brain, and so delicate is their sensitiveness that the hearer perceives not only the degree of loudness, but even the finest quality of a sound, the harmony of tones, and the distance from which it comes. The moment that life becomes extinct, however, the spiral shell of nerves collapses and the marvelous organ is a dead thing, unsatisfactory to the investigating anatomist. If only it had been found possible to examine the internal structure of the living ear, aural surgery might perhaps amount to something to-day."

Artificially Colored Flowers.

At the last meeting of the California State Floral Society, Mr. Emory E. Smith read the following, which is replete with interest to all lovers of flowers:

Every now and then some one starts a story of having seen flowers of unusual colors, such as blue roses, red calla lilies, green violets, etc. These seeming freaks are always a seven days' wonder to those who are not familiar with the method by which they are obtained. For many years it has been a well-known fact that flowers when dipped in certain chemicals would rapidly change colors to such a degree as to be almost unrecognizable as the same variety. The public in general has known but little of the methods employed. M. Fipol, a distinguished savant, recently exhibited to the Scientific Association in Paris the results obtained by subjecting flowers to the influence of a mixture of sulphuric ether and ammonia. A quantity of ether is poured into a glass and to this is added a small quantity of liquid ammonia, say one-tenth of the volume.

The flowers are then plunged into the fluid and with the most surprising results. Those which are naturally red or violet in color, take upon themselves a bright green tint. Flowers, the colors of which are variegated, assume as many different shades; for instance, the upper petal of the sweet pea would become dark blue, while the lower petals would turn a bright green. White flowers usually assume a yellow color. Red geraniums turn blue, and red snapdragons become brown. Yellow is seemingly the only color which the solution does not affect. The action of the liquid is very rapid, and colored spots can be procured upon the flowers by pouring here and there a drop of the solution. Flowers which are many colored are sometimes changed to the most remarkable novelties that it would be possible to imagine. After the flowers have been subjected to the liquid, they should be plunged in pure water, when they will retain their new tints for several hours, but will gradually assume their natural colors.

CONTROLLING SEX.—In considering the causes which determine sex in animals, we are irresistibly led to include the fact that the sole difference between a queen bee and a neuter gender worker bee, is that to produce the first, the egg is given a larger cell, and the larva is fed upon a higher grade of food. There is no doubt of this fact, and so we may use it as an illustration of one of nature's methods, and as a hint to utilize the knowledge so gained. If extra care, extra food is required in one branch of creation, why may it not be also as powerful an agent in any other. Let cattle breeders who especially desire heifer calves proceed on this plan. Keep the mother cow in perfect health previous to copulation, give her the best care, the best quarters, the most nutritious food, and treat her as if she was really to produce a queen of the dairy. This process can do no possible harm, will insure a perfect calf, and if it should result in bringing a heifer in seven cases out of ten, there will be fewer

bull calves of but little value, and more heifers, which are of the most value for dairy purposes. We commend this to breeders as a judicious course in every case whether the producer is male or female.

Telescope and Microscope Lenses.

R. B. Tolles of Boston, according to the *St. Louis Globe-Democrat*, was the most successful maker of microscope lenses the world has ever seen. He recently died, but while living, occupied the same relation to his business, as maker of microscope lenses, as does his neighbor, Alvan Clarke of Cambridge, to his business of making telescope object-glasses.

Mr. Tolles, some years ago, produced a microscope lens which magnified 7500 times. It was the first and only one ever constructed, and was made as the result of a long controversy with other microscopists in regard to the possibility of resolving what was known as Nohet's nineteenth hand.

Nohet was a Frenchman, who, by mechanical appliances, ruled on glass parallel lines at the rate of about 100,000 to the inch. No microscope lens then made was sufficiently powerful to count these lines. Mr. Tolles started to make an objective that should magnify 7500 times. This he succeeded in doing about 1874. This objective was one seventy-fifth of an inch in diameter, and is about as large as the hole made in a sheet of paper by the point of a very fine needle. This lens was afterward sold for \$600 to Major Woodward, in the Government employ at Washington. He sold it to Dr. Ephraim Cutter, in whose possession it now is.

Objectives that magnify 5000 times are rare, and it is a "powerful microscope" that magnifies even 2500 times. These are necessary in bacteriological research, and in testing blood corpuscles to determine whether they are of human blood or not. A local paper recently told of a Boston Physician who examined the tubercle bacillus with a glass that magnified 900 times. Ridiculous! You can't see the consumption bacillus with an objective that magnifies less than 1200 times. England is the great rival of this country in microscope making.

If an object-glass is ever made that will magnify 10,000 times, it will be a more difficult task than making a telescope glass twice the size of the great glass in the Lick telescope.

THE REACH AND SCOPE OF INTELLECT.

Every man is fitted to fill some position of importance. Every man's mind is more or less expansive, more or less reaching, more or less comprehensive. The man who loves his profession always possesses an inquiring mind; he is judiciously inquisitive; he guides his inquisitiveness in the line of his profession; he is a learner and a teacher. If he becomes a mark among men, the mark is always in proportion to his success. If he confines his investigations to a scientific line, he discovers and applies the truths which govern his operations. This makes him a successful man; if a farmer, he is ready for all emergencies, he succeeds because he understands nature's laws and her demands. His crops are always fair, almost always good, generally superior, and he flourishes like a green hay tree.

A CURIOUS PHENOMENON IN ELASTICITY.

If a strip of gum rubber be heated, then expanded, and quickly wound round and round upon a metal tube or wire, and then cooled for a short time in cooling mixture, it immediately loses all of its elasticity and has no tendency to contract. If, however, it is then put into hot water, it at once regains its elasticity and returns to its original length. Another way of observing this same phenomenon, is to hold the heated rubber a second in an expanded condition when unvulcanized, when it will retain its shape. If, however, it is now immersed in hot water, it contracts to one-fourth or one-fifth of this length, and will remain contracted to one-third or one-fourth of its original length. These are what may be called the secondary effects of elasticity.

TELEPHONING ACROSS THE ATLANTIC.

Experiments are now being made to ascertain if it is possible to communicate with America by telephone. Of course the ordinary telegraphic cables are being used, but it will, no doubt, be necessary to lay a special cable for this purpose when it has been demonstrated clearly enough that conversation can be carried on from such a distance. We understand that sound can be heard the other end, with the apparatus now in use, but as in telegraphy, so in telephony, a specially delicate form of instrument will have to be designed before perfect success will be obtained. The telephone in London was recently connected through to Marseilles, and conversation was carried on with great success.

WHY THE EAGLE CAN LOOK STEADILY AT THE SUN.

The eagle is enabled to look at the sun by reason of a thin, semi-transparent veil, which can be instantaneously drawn over the front of the eyes. It is known as the nictitating (i. e., winking) membrane, and acts as a screen to shut out the too great intensity of light, so that with its assistance the eagle can confront the sun even at noonday. The membrane is so fine as not to obstruct the sight when drawn, like a curtain, across the pupil, and when not in use lies folded up in the inner corner of the eye.

GOOD HEALTH.

IDIOTS.—An interesting experiment was made recently at the great idiot asylum of Parle. A kind of Punch and Judy show was exhibited before the inmates, with a view to ascertain whether any impression could be made by it upon their dormant intelligence: "About 1100 idiots were assembled in the gymnasium of the institution, most of whom had made some slight progress toward intelligence. Many of them had learned to tie their own shoes; others could dress themselves, with a little assistance; others could feed themselves pretty well; all had learned to sit still, and most of them could imitate the easier motions of their instructors. When they were seated and in order, the curtain rose, disclosing a small stage. The play presented was called 'A Dentist's Pupil,' and the fun of the piece was chiefly due to the vigor with which the hero plied his endgel. At first the physicians were inclined to believe that the experiment was going to be successful. The unfortunates applauded the endgellings in their uncouth way, making loud ontories and laughing holsterosely. It seemed that there was but one perfect idiot in the whole assembly—a dwarf, with a huge, mishapen head, who had been exhibited at fairs under the name of the 'King of the Esklmos.' He alone remained quite passive during the whole play. When the performance was over, the company relapsed at once into their nasal silence and vacancy. There was no exchange of impression, no after-glow of interest, and, what was more discouraging, they appeared to have no recollection of what had occurred. The conductors of the experiment were obliged to conclude that the play had had no effect in rousing or stimulating intelligence."

Too MUCH SHADE.—Houses in places otherwise unexceptionable are often so closely overhung with trees as to be in a state of humidity by the prevention of a free circulation of air and a free admission of the sun's rays. Trees growing against the walls of houses, and shrubs in confined places near dwellings are injurious also as favoring humidity. At the proper distance, on the other hand, trees are favorable to health. On this principle, says Dr. James Clark, it may be understood how the inhabitants of one house suffer from rheumatism, headache, dyspepsia, nervous affections and other consequences of living in a confined, humid atmosphere, while their nearest neighbors, whose houses are otherwise situated, enjoy good health; and even how one side of a large building fully exposed to the sun and a free circulation of air may be healthy, while the other side, overlooking shaded courts or gardens, is unhealthy. Humid, confined situations subject to great alternations of temperature between day and night, engender the most dangerous of all the physical qualities of the air, and humidity in general is the most injurious to human life. Dryness, with a free circulation of air and a full exposure to the sun, are the material things to be attended to in choosing a residence.

CITIES DETRIMENTAL TO EYESIGHT.—That "we are all poor critters," as the Widow Baddott quoted her late husband's saying, is but too well proved by noting the percentage of thin, scrawny, pale and otherwise defective people in any crowd; but of late the doctors have presented appalling proofs that city-bred people are unusually "poor critters." Their greatest defect is in the eyes. One-third of all the city people are more or less near-sighted. The tall buildings limit their range of vision, the invisible dust, even more than the visible, injures the eye, and the wearied organ is not restored by gazing over the green fields and far away. The narrow walls of the home or playground or schoolroom shut the children in during their growing years, and the eye, habituated to so short a range, loses half its capacity. The truth of this is proved, and more's the pity.

THE CHIN IN WALKING.—Much care and thought should be exercised in walking. The shoulders should be kept up and square; the chest should be expanded. The chin is the pivot upon which largely depends the poise of the machine. Step out easily and firmly, letting the ball of the foot strike the ground first, so that you get the benefit of that beneficent little spring which Dame Nature has built into your instep to save the rattle and jar to the whole system, which people who will walk on their heels inflict on their anatomy.

GIRLS WITH THEIR SCHOOL BOOKS.—The habit of young girls carrying their school-books under their arms, or in bags or portfolios hung from their arms, is said to be to distort the figure. German doctors are exhorting parents to provide young girls between the ages of 11 and 14 with knapsacks for carrying their school-books.

THE BLOOD IN PNEUMONIA.—Dr. Kikodze, a specialist, has been devoting his attention to the condition of blood in the human body during pneumonia, and found that during the course of this disease, the white corpuscles increase in number as much as three times what they are in healthy persons.

THE DEEP CREEK MINES. of which so much is being said at present, lie partly in Nevada, The Dugway and Fish Springs mines are wholly in Utah.

USEFUL INFORMATION.

Animal Intelligence.

Animal intelligence is quite as common and pronounced whether we observe it in the largest of the species or in the families of insects. The ant is proverbial for its intelligence. Even the loathsome spider is quite remarkable for the intelligence it sometimes exhibits. This insect is quite as susceptible of being tamed as any other species. A European semi-scientific journal, the *Month*, relates the following in regard to

The Spider.

It is a well-known fact that spiders have power of discrimination, and are able to discriminate between friends and foes, approaching those whom they have found to be friendly, while avoiding strangers. One lady succeeded so well in taming spiders to recognize her, that they came down to be fed whenever she entered the room where they were kept. Dr. Moschen, of Leipzig, relates that in Oderwitz, where he lived for a time, he noticed one day in a rather dark corner of the ante-room a tolerably large spider's web, in which a well-fed spider had made its home, and sat at the nest-opening, early and late, watching for some flying or creeping food. He was accidentally several times a witness to the craft with which it caught its victim and rendered it harmless, and it soon became a regular duty to provide it with flies several times a day, which he let down before its door with a pair of pincers. At first this feeling seemed to arouse small confidence, the pincers, perhaps, being in fault, for it let many of the flies escape again, or only seized them when it knew they were within reach of its abode. After awhile, however, the spider came each time and took the flies out of the pincers and spun them over. The latter business was sometimes done so superficially, when flies were given quickly, one after the other, that some of the already ensnared flies found time and opportunity to escape. This game was carried on by him for some weeks, as it seemed ominous. But one day, when the spider appeared ravenous, and regularly flew at each fly offered to it, he began teasing it; as soon as it had got hold of the insect, he pulled it back again with the pincers. It took this exceedingly ill the first time; however, as the fly was finally left with it, the indignant spider managed to forgive him, but, when later he took the fly quite away, their friendship was destroyed forever. On the following day it treated the offered flies with contempt, and would not move, and on the third day it had disappeared from its abode altogether.

The Elephant.

Passing from one of the smallest orders of creation to the largest, we come to the elephant. The *London Spectator*, in one of its late issues, gives the following in regard to an elephant which could evidently count up to 20 and could not be cheated out of his count. One Arthur Clay sends the following to the above-named journal:

It was told me, he says, by Mr. Quay, at the time a non-commissioned officer of the First Battalion of the Sixtieth R. Rifles, but now one of her Majesty's yeoman of the guard. In 1853 his regiment was marching from Peshawar to Kopulvie, and was accompanied by a train of elephants. It was the duty of the mahout in charge of each elephant to prepare 20 chupatties, or flat cakes made of coarse flour, for his charge. When the 20 chupatties were ready they were placed before the elephant, who, during the process of counting, never attempted to touch one of them until the full number was completed. On the occasion related by Mr. Quay one of the elephants had seized the opportunity of his mahout's attention being attracted for a moment to steal and swallow one of the chupatties. When the mahout, having finished the preparation, began to count them out, he of course discovered the theft and presented his charge with 19 in place of the usual number. The elephant instantly appreciated the fact of there being one less than he had a right to expect, and refused to touch them, expressing his indignation by loud trumpeting. This brought the conductor of the elephant line (with whom Mr. Quay had been in conversation) to the scene. Having heard the explanation of the mahout, the conductor decided that he was in fault for not keeping a better lookout and ordered him to provide the twentieth cake at his own cost. When this was prepared and added to the pile, the elephant at once accepted and ate them.

WRITING ON THE CAR.—There are two ways of writing on a train. The first requires that the paper be laid upon a light board, perhaps 18 inches square; one end of this will rest in your lap and the other end farthest from you will be raised a few inches by a cord which passes around the neck. The whole affords a sloping desk which moves with the body and is fairly satisfactory. The simpler, and perhaps the better plan, is to place your tablet upon a feather pillow in your lap, when you will find that the elasticity of the feathers reduces the motion to a minimum and make writing easy.

AN AUTOMATIC LIFE SAVING BELT has been tried in the Thames. It can be screwed up like a hall and fired from a cannon or thrown by hand, the belt righting itself by contact with the water.

ELECTRICITY.

A NEW STORAGE BATTERY.—The *Electrical World* of May 16, contains a description of a new storage battery, which, it says, "promises better things than have up to the present time been obtained" in this form of electric traction. The chief peculiarity of the new system is the use of an improved form of the alkaline storage battery, instead of the old lead accumulators that have been a constant source of trouble and expense to those who have undertaken to use them for traction purposes. The chemical actions in it are comparatively simple, and are found to be almost completely reversible, so that the tendency to deterioration is very small. Its adoption has enabled Messrs. Waddell & Entz, the inventors, to reduce the weight of battery required for a 50-mile run of a car to 3000 pounds, instead of the 4000 or 5000 which have usually been employed in cars operated by the ordinary batteries. The motor is arranged to be reversed and to operate as a charging dynamo while the car is running down grade or stopping. In this way a certain proportion of the energy spent on the car is recovered. The experimental trips of the new car have been unusually successful, and give promise of commercial practicability, which is more than can ordinarily be said of storage battery cars. The secret of success probably is, after all, the lightness of the whole car equipment, thus greatly reducing the amount of power necessary to operate the car.

ELECTRIC CARS, LIGHTS, ETC., RUN BY WATERFALLS.—In the town of Dover, on the Salmon Falls River, on the division line of Maine and New Hampshire, the water power furnishes not only light and heat to that town but to several distant towns also. Power is also furnished to a street railway seven miles in length. The water wheel has a capacity of 500 horse power.

In Greenwood Springs, Colorado, the electric lights, mills, pumps, hoists and tramways are successfully run miles away from the power station at the falls. In Ireland, the Giant's Causeway electric railway, eight miles in length, derives its power from two turbines that drive dynamos which deliver electric power to the motors of the railway.

At Burgenstock, near Lucerne, Switzerland, there is an electric mountain railway a mile in length, operated by two dynamos of 25 horse power, worked by a water-wheel of 125 horse power. Between Pazzala and Lugano, in Italy, there is a waterfall which supplies 300 horse power to run two dynamos, one for working tramway motors, the other supplying nearly 2,000 lamps at the hotel and private buildings.

DEVICE TO PREVENT STEALING OF TELEGRAPH MESSAGES.—The Belgian military telephone system has just been put into service. The essential feature of such a service was that messages could not be stolen by tapping of the wires and the insertion of a receiver. This danger was electrically without remedy by any known appliance, so its solution was temporarily made by placing a peculiarly constructed bell at the receiver, which would automatically tap at the precise moment of beginning and of ending conversation. In this way operators could be sure, by a system of countersigns, that they were in communication with the proper parties before talking secretly. Then the bell would sound an alarm in case the circuit was interrupted for any purpose.

ELECTRICITY IN THE UNITED STATES.—One-third of all the telegraph lines, one-half of all the telegraph wire, and one-quarter of all the telegraph stations in the world are within the United States. In 1890, there were 800,000 miles of wire and over 24,000 offices, quite a contrast with the 80,000 miles of wire and less than 2,400 offices in 1866. Now they transmit not far from 70,000,000 messages in a year. The submarine cable systems of the world stretch over 120,070 nautical miles, the ten European-North American cables representing 23,000 miles, over which 10,000 messages daily pass between the two continents. Without the co-operation of telegraphy what would the business of the world amount to?

UTILIZING NIAGARA FALLS FOR ELECTRICAL WORKS HAS BEEN COMMENCED.—The Falls Park Commissioners have made an agreement with a strong syndicate of English capitalists, the owners of large electrical works at Deptford, England, who have deposited \$20,000, which is to be forfeited if the operations for the utilization of the power of Niagara Falls are not begun before March 1, 1892.

ELECTRICITY IN MINING.—To-day, there are between 30 and 40 mines in this country using electricity for either illuminating or power purposes, and with such success that electric mining engineers look, in the immediate future, for an immense demand from many of the mines of this country.

BLACK GRAVEL.—The *Trinity Journal* says that prospectors in Siskiyou county have lately struck some black gravel on what is called Greenhorn Gulch, which contains a large amount of the precious metal. The gravel and gold is almost jet black and promises to equal, if not excel, the famous blue gravel discovered in that county.

ENGINEERING NOTES.

TO REMEDY SWAYING AND OSCILLATION.—Frequently the oscillations of the main belt in a mill come in unison with the beat of the engine, and a pretty perceptible slapping about the belt is noticeable, says the *Artisan*. The beat of an engine will often come in sympathy with the rhythmic sway of the building, and so increase it as to be very perceptible. If this were continually going on, in exact time, it would become so great in time as to be dangerous, but one or the other gets ahead and mixes the movement, so that it gradually ceases until they are again in unison. If the speed of the engine is changed in either case, the swaying will be kept mixed all the time instead of occasionally. On long lines of shafting this will appear also, the pull on the belt at the commencement of the stroke being in unison with the spring of the shaft, thus causing a marked oscillation. The same remedy is applied here, to mix the two movements purposely, and the trouble is partly removed, if not entirely.—*Ex.*

FILTER FOR WASTE OIL.—Among the ways for freeing oil from dirt and impurities, a good one is to stir it up with a hot solution of washing soda, and settle in a warm place until the oil is quite clear; then run off the water at the bottom of the vessel. If you prefer to filter it, a very simple filter is made by knocking out the bottom of the box and covering it with gauze wire; then place a layer of cotton wool over this, and pour the oil through it. The former process is much preferred, although it is more troublesome, because it not only extracts the solid dirt, but also extracts dirt out of solution in the oil.

IN COTTING THREADS IN AN ENGINE LATHE where the lead screw is used, many have wondered why the clamp nut could not be thrown out and in instead of running the lathe backward so much, nearly half the time at least. The trouble all seems to be in locking in the clamp nut at the right moment. With some threads it would be impossible to lock it in wrong, and with others it would be hard to catch it at the proper instant. In either case, it is better to leave a few extra threads as guides to show the position of the thread tool before it comes to the thread proper, and turn off the dummies afterward whenever there is a chance.

GRAVITY, it is said, always acts downward, and so it does, but the effect that it produces is not always found in the same direction. A weight attached to a fly-wheel hangs toward the center when it comes on the upper side, and draws away from it when it arrives in the lowest position; but under a high speed the force of gravity gets belated to such an extent that this in-and-out action comes nearly horizontal. The same thing is seen when a wheel is running out of true. If an object is held up against it, the wheel seems to be affected more on the opposite side than at the place where the blow was received.

SKILL IN USING THE SAW.—Almost any one can run a hacksaw for awhile, but there are a few who can make them hold out as long as they ought. The knack is said to lie in a true hand that can draw and drive them without any sideways motion, and keep a constant pressure on the work; but we find that a firm and steady grasp has something to do with the business that will hold a saw to its work and not let it get the upper hands when stepping from thick into thin stock.

DRIVING SHAFTING.—Why does it take eight times the power to drive a shaft of a given diameter that it would one which is only half as large in diameter? It is owing to the weight being increased four-fold whenever the shaft has been made twice as large in diameter, and the space the resistance has overcome being in direct proportion to the circumference in both cases.

A good illustration of how the fibers of cotton will catch on to everything is shown in the machine shop when a nut is tapped out a little too small, or the adjustable die-plate left a little large. A piece of cop waste is wrapped around the tap, and once more made to find its way through the nut, with the result of making it more easy on the bolt.

AN OLD BELT.—The *Westbrook Chronicle* says: "There is an old belt in the first mill built at the Westbrook Manufacturing Co.'s plant, that has been in constant use since the mill was built in 1831, and will stand many years of wear yet." The cattle of '31 must have had tough hides, or the tanners of those days more skilled than those of the present day.

BELTS.—It has been said that the best way to run a belt is to use three thin ones, one over the other. About all the two outside belts could do would be to hug the inside belt to the wheels and let it do all the work while the others are being chafed to pieces. Better rivet them all together into one solid belt.

The colnage at the San Francisco Mint for the month of May was as follows: Double eagles, \$880,000; standard dollars, \$550,000; dimes, \$46,075; total, \$1,476,075.

Passing Events.

It is noted elsewhere that the Anti-Debris Association is bringing more suits against hydraulic miners and actively continuing the fight against this industry. In due time, the memorial of the Legislature will doubtless be acted upon by Congress, and steps taken by which the gravel miners may work the mines without injuring the farming industry along the rivers.

River mining, which has not been prosecuted to a great extent of late years in this State, shows signs of a revival, owing to the fact that there is less debris in the rivers than formerly and the old method of wing-damming may be more readily applied to get at the river bed.

There are rumors that the mints will shortly cease the coinage of silver dollars, here and elsewhere. There are in the Branch Mint in this city \$36,000,000 in silver—all dollars—but there is storage room for as much more.

The scheme of working the material in the Carson river by means of a dredge will shortly be tested, after a long delay.

California the Staid and Even-Going.

While the business of mining at many of its important centres elsewhere seems to be just now considerably depressed, no complaints of this kind are heard from any part of California. In the Wood River country, Idaho, as also in some of the big camps of Montana, mining operations are less active than formerly, nor do certain districts in Washington appear to have made as rapid progress as was expected, nor as rapid as their acknowledged merits would seem to have warranted.

This depressed condition of mining affairs is imputed to a stringent money market, tending, not only to restrict investments, but also to check operations in the products of these mines, which consist mainly of lead and copper. To this there might no doubt justly be added an element of speculation, something of a "boom" having of late obtained throughout these several countries, where a halt has been called in the growth of the leading cities as well as in certain branches of mining. Neither Denver, Hailey nor Leadville have forged ahead the past year as in more prosperous times was their wont. All have found it necessary to slacken their pace somewhat, waiting a little till the mining industries catch up. This check is, of course, but temporary, nor has it anywhere caused serious embarrassment to any interest or branch of business in these great and onward moving countries.

Reverting to California, it may be observed, that we have experienced here no mining hitch, nor has the business of late been at all intermitted. Bullion production has every where been steady if not rapid, one reason of this being that the output of our mines consists mainly of gold, always marketable at a fixed and remunerative price, which can hardly be said of lead and copper, or even silver. Mining with us is therefore characterized by a certainty and a stability not common to the business in the other States mentioned.

And as mining has gone on with so little change, so has the growth of our cities and towns been equally steady, this being especially true of San Francisco, which, if it has not hounded ahead, like many other Western cities, has increased year by year, keeping abreast of her business, without outgrowing the same, or drawing unduly heavy drafts on the future. She has, in fact, never built much beyond her actual and immediate necessities.

San Francisco has, in years gone by, had her set-backs, but they were never ruinous. And California has had her mining failures. But these, too, are of the past. Not for a long time has any large amount of money been lost through investments in our mines, nor is it probable that much will be lost in the future. Of all our industries, gold-mining has come to be the most safe and the most sober. Of this once last State it may even be claimed that she has, as a whole, become eminently staid and conservative, if not a little slow going. But if some of her younger neighbors have seemed to outstrip California in the race for population and wealth, this has not excited in the breasts of her people either jealousies or heart-burnings, so largely have these countries been colonized by her and so nearly are we all identified in interest and feelings.

The Later Rains and Their Effects.

Commencing on Wednesday evening a drizzling rain, slight but continuous throughout the night, fell in this city, the precipitation in various localities farther north having been much heavier. This recent rain, with the occasional showers that fell all through the month of May, has constituted this an exceptional spring in California.

As the hay harvest is now well advanced, and that of grain already begun, these unusual and unwelcome showers have caused the hay-makers much inconvenience, and in certain localities, some considerable loss. It is our wont to lay great stress on these slight rains, which, when they occur, fail not to provoke both comment and complaint everywhere in California; the long dry seasons on which we can count with so much certainty, having tended to spoil our people in this respect.

Throughout the entire Atlantic region a two-days' steady rain in harvest-time is a common occurrence. There, too, heavy thunder showers come up on the instant, and falling in a deluge, drench the hay and grain when, perhaps, just

well-onred and ready for the barn, necessitating their being spread out and dried again, the farmer being fortunate if this process of drying is not forced upon him more than once. A little experience like that would lead the average Californian to better appreciate the many climatic advantages he enjoys, if it did not cause him to cultivate more painstaking, and serve to develop in him more fully the virtue of patience.

Scarcity of Miners Abroad.

There are complaints in New South Wales regarding the scarcity of good hard-ground miners, and the progress of the mining industry is retarded for want of suitable labor. The fact that good miners are in strong demand is sufficiently shown when the famous Broken Hill Proprietary Co., one of the strongest mining companies in the world, is under the necessity of advertising for steady men at 10 shillings per shift of eight hours. This is a leading company at a great mining center, so other companies in more sparsely settled districts must suffer even more for lack of competent labor.

This seems strange when it is known that never in the history of Australia has there been a time when so much attention was given to mining enterprises, or when so much labor and capital was embarked in the industry as at present. Miners are found, not as solitary prospectors, but in strong parties and groups of parties carrying on systematic work in nearly every accessible area of the continent.

The Australian Mining Standard says that one cause contributing to the present scarcity of miners is "probably the fact that a vast amount of work which miners can best perform is now being done in connection with railway sewerage and other public works in the mother colony. Then again, the colonial youth does not take kindly to the miner's occupation, and the lack of in-migration on his part, combined probably also with lack of proper provision for training boys in mines has left us without a sufficient number of recruits to fill gaps in the ranks of the older workers, and to meet the increasing necessities of a growing industry."

Whatever the causes, it is evident from the local papers that the position in New South Wales is a serious one, and in many instances operations are either being carried on at a great disadvantage or are absolutely suspended for want of competent labor. There are plenty of men of a certain sort to be had, but they are next to useless for the work required of them. The climate in the districts where labor is most in request is favorable, and the general conditions of life are such as to meet all reasonable requirements. The wages of miners in the districts of Hillgrove, Bengara, Wellington and Lewis Ponds are £2 10s. per week, and Broken Hill £3 per week.

More Mining Injunctions.

The special counsel for Sacramento county in the suits against the hydraulic mines secured recently an injunction from Superior Judge Davis of Yuba City, against eight mines on the North and Middle Forks of the American river. The papers have been served and the mines have stopped work. The agents have been on the scene ever since, and state that up to date the mines have continued to obey the order. Two or more have signified their intention to fight the cause, but none of them appeared to be willing to defy the order of the court and run the risk of suffering the heavy penalty attached to the violation thereof.

The parties enjoined are: S. M. Pragne, mine located on the ridge in Indian canyon, North Fork of the American river; the claims formerly known as the Washington and Blue Wayne; W. R. Morton, in the vicinity of Indian canyon; Rudolph Dekouse, on the North Fork, whose tailings dump into Indian canyon; A. Rosetti, on the North Fork of the American river; Henry Del Ray, on Iowa hill, whose tailings dumped into Indian canyon; Alexander Rossi, Homeward Bonnd claim, which dumps into the North Fork; G. M. Lihby, near Indian canyon; Parker, near Indian canyon.

In addition to these suits brought in the State court, a number have been brought in the United States Circuit Court in the name of the Federal Government. In such of these last named suits as affect the miners on the American river, Sacramento county will push the prosecution through its special counsel.

The Anti-Debris Association will prosecute such of the cases as affect Yuba and Sutter counties. The persons who have been proceeded against in the Circuit Court, and who come within the jurisdiction of Sacramento county, are O. J. Spencer, W. O. Spencer, J. F. Brown, J. D. Pursley, J. F. Brown Jr. and a man named Gleeson. Mr. Devlin, the special counsel, states that he has several other suits in preparation.

George Ohleyer, President of the Anti-Debris Association, says there are 40 hydraulic monitors operating in Plumas county, notwithstanding the injunctions. Other members of the association, of whom the Marysville Appeal has made inquiry, said the outlook is not very encouraging.

Electric Roads.

Work on a new electric railroad was inaugurated at the junction of Page and Clayton streets on Monday, C. E. Mayne, President of the Metropolitan Railway Co., digging the first spadeful of earth. The first portion of the road will be built from Clayton St. east, as the franchise calls for, to Market St., and a mile is to be completed before July 1st. The real estate agents present and those who have so far expressed an opinion as to the effects of this road upon South Side real estate predict that its effect will be most beneficial, and will certainly stimulate a great activity in this section before fall. The road should bring into market great numbers of residence lots.

It is to be hoped, however, that the company has carefully considered its electric plant, for we have had too many failures in this State already. The last extensive electric road built, that from Oakland to Berkeley, only ran a few weeks, and then had to stop to have an entire change of its electric plant. It is explained that the motors burned out, or that the power was insufficient; but whatever the cause, the fact remains that, under the plan adopted, the cars had to stop running.

This is the fourth or fifth instance of the kind we have had in California, and it has naturally caused a distrust of electric roads. It is understood, of course, that they run successfully elsewhere, and it seems strange that the electricians who have had charge here have been unable to arrange its appliances satisfactorily. Cable roads are built and operate steadily from the first day. There is no apparent reason why electric roads cannot be made to do the same. But the experience here with electric roads has by no means been satisfactory up to this time. Notwithstanding this, more are projected and being built, and some are operating all right. But the projectors should exact a guarantee from its electrical supply companies, and they ought to get competent men and proper machinery in the first place, and not experiment with other people's money.

Silver Coinage.

It is expected here that the coinage of silver at the Branch Mint will shortly be stopped wholly or in part. No orders have yet been received by the superintendent to reduce his working force, but it is intimated that the end of this month, which closes the fiscal year, will see the dismissal of a number of the coin-makers. There are now in the vault of this Mint \$36,000,000 in silver, and there will be \$1,000,000 more by the end of June, but there is plenty of room for as much more, so the reason for suspension of coinage is not lack of vault room.

This proposed stoppage is the result of the law passed by the last Congress. After the 1st of July the Mints will only coin what is demanded, and the rest will be stored. The Mints are required to purchase monthly up to 4,500,000 ounces if presented for sale, and this silver will be stored instead of coined. All the silver in the Government vaults on this coast and at the East has silver certificates issued against it and the certificates have gone into circulation. This is to be the policy in the future—issuing silver certificates against all silver bullion purchased, so that it makes very little, if any, difference whether it be coined or remain intact, so long as the certificates circulate.

THE PATENT OFFICE at Washington has a printed circular which it sends to inventors of machines for "perpetual motion," setting out the fact that the thing is an impossibility.

Mine Timbering.

The square system of timbering, in use in most of our large mines here on this coast, was first introduced in Australia by Mr. W. H. Patton, who adopted it in the Broken Hill Proprietary mines, although it does not seem to be so satisfactory to the people there as to our miners, who are more familiar with it. The accompanying description and plans were furnished by Mr. Patton to the report of the Secretary of Mines for Victoria:

"The idea is supposed to have originated in the German mines, but in a crude form. It was introduced among the mines of the Pacific Coast of America some 20 years ago, by a gentleman named Diederheimer. Its use there is universal, and experience has evolved it from the embryo state to its present perfection. The old system and its accompanying disadvantages

inches; they are moved from place to place as required, and upon them the men stand when working in the stopes and in the faces. A stope resembles a huge chamber fitted with scaffolding from floor to roof. The atmosphere is cool and pure, and there is no dust. Stage is added to stage, according as the stoping requires it, and ladders lead from one floor to the other; the accessibility to all the faces is a great advantage.

If, while driving, a patch of low-grade ore is met with, it can be enriched by taking a higher class from another face, and so on, any grade can be produced by means of this power of selection. Opinions have been expressed that this system of timbering is not secure, and that pressure from above would bring the whole structure down in ruins. But an opinion such as this is due to miscomprehension of the facts. If signs of weakening in the timbers become

Hamilton Corliss Engines.

We illustrate on page 269, the Hamilton Corliss engine of a compound tandem type. These engines are so well known that it is unnecessary to describe their perfect proportions, high finish and general excellence.

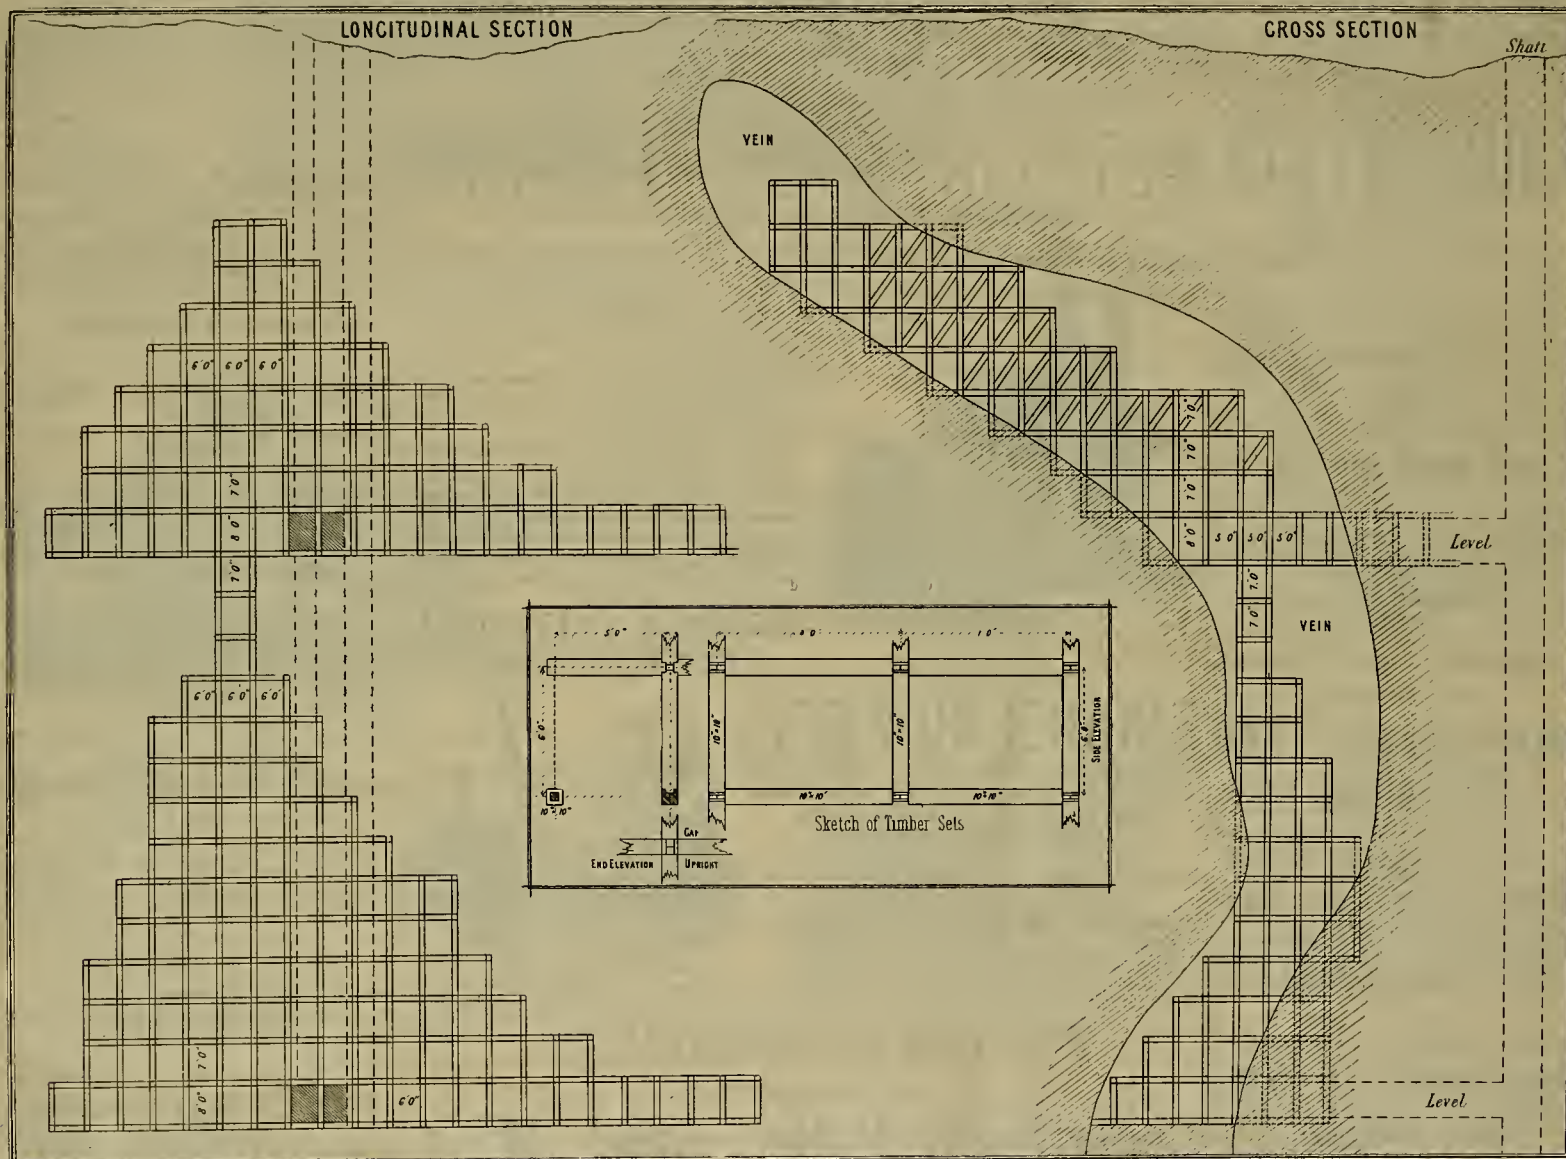

This company has one of the largest, if not the largest works in this country for solely manufacturing Corliss engines. As they confine themselves to the building of these engines, they have been able to arrange their works with a complete line of special tools for their production, insuring low cost, and at the same time absolute accuracy in all details.

This company is prepared to guarantee on their engines a water consumption duty of 13½ pounds of water per horse power, per hour, on their triple expansion engines, and 15 pounds on their compound condensing. This is

trio Light Company of St. Louis, eight. We mention these two out of the many electric light companies using the Hamilton Corliss engines, as they are the largest companies in existence. These engines are represented by Messrs. Rix & Birrell, No. 38 and 40 Fremont St., who are sole agents for the Pacific Coast.

Important Mining Decision.

Judge Hawley, presiding in the U. S. Circuit Court at Carson City, Nev., has decided the case of Walcott vs. Watson, involving a one-half interest in the celebrated Joanna mine in White Pine county, Nev. The decision related to the removal of the case under the Act of Congress of August 13, 1888, from the State Court to the Federal Court on the ground of local prejudice and influence. Mrs. Walcott brought the suit in the State Court for one-half

PLAN AND SECTION SHOWING THE SQUARE SYSTEM OF TIMBERING IN MINES.

are well known. A drive would be put in for a certain distance, when it had to be abandoned until it could be filled up with waste material and made secure. This process entailed much expense. The staff had first to be broken on the surface, then sent below, trucked along the drives, and finally shoveled into place. Ventilation was impaired and the drives were filled with dust. The men worked in discomfort, and were not in a condition to perform a full measure of labor. Under the system as adopted in the Proprietary mine, these disadvantages disappear. The cost is one-third less, ventilation is perfect, and every portion of the faces are accessible at all times. Sawn timber is used throughout, the upright and cross-pieces are 10 inches by 10 inches, and stand 4 feet 6 inches apart; along the course of the drive, the cross-pieces are 5 feet in length, and the height of the main drives and sill-floor sets are 7 feet 2 inches in the clear. In looking out the stopes, the uprights are 6 feet 2 inches, just one foot shorter than those in the main drives. The caps and struts are of the same dimensions and timber as the sill floor. The planks used as staging are 9 inches by 2½

apparent, the remedy is very simple. Four or more of the uprights are lined with planks, and waste material is shot in from above, and a strong support is at once formed, or if signs of crushing are noticed, it is possible to go into the stopes, break down ore, and at once relieve the weight.

HENRY EDWARDS, the actor, died in New York on Tuesday. He was well known in this city where he was one of the founders of the Bohemian Club, and a leading member of the California Academy of Sciences, of which he was for several years the honored vice president. Mr. Edwards was an entomologist of distinction and had one of the largest entomological collections in the world. He made special studies of lepidoptera and coleoptera. Mr. Edwards was one of the most genial of men, greatly liked by all who knew him. He wrote a great deal on entomological subjects and described some 300 new species in this country.

THE British House of Commons is considering a proposition to make the insurance of miners' lives compulsory in Scotland. It is enforced in many of the English mines already. It is proposed to pay the premiums by deducting a small amount monthly from the pay of the men.

the basis on which all makers of high-class engines contract in the Eastern States, and is almost unknown on this coast. This insures both a high economy and perfect proportions, and through this close competition on these guarantees, the present high perfection of these engines has been attained.

All these engines are built by the use of jigs, thus making all duplicate parts exact duplicates of the parts furnished originally with the engine. Their handwheels are turned off on the engine shafts on which they are to run, thus insuring their being absolutely true in service.

The Company has built up to date more than three thousand of these engines, in many cases receiving from the same Company orders that ran through several years, for five to ten engines, showing the entire satisfaction they have afforded them. They have at this date orders ahead for over forty engines at their works. These engines are specially designed for electric light and road service, and for the use of flour mills.

In New York, the Manhattan Electric Light Company has twelve, and the Municipal Elec-

of the mine and an accounting. Watson filed an answer in the State Court denying the claims of plaintiff and setting up a counter claim for \$40,000 against Mrs. Walcott. Mrs. Walcott thereupon, being a citizen of California and Watson of Nevada, although she was plaintiff on the record, filed a petition for the removal of the case to the Federal Court on the ground of local prejudice and influence against her, asserting that as to the counter claim she was defendant. Judge Knowles of Montana made the order to remand and counsel for Watson moved to remand. Judge Hawley held that the case was properly removed, and that it is now and has been since the order of removal in the U. S. Circuit Court.

The State Court, notwithstanding the order of removal, tried the case ex-parte and rendered judgment for Watson. The attorneys for Mrs. Walcott relied upon the order of the Federal Court and were not present at the State trial. The decision of Judge Hawley was a victory for Mrs. Walcott and the cause must be tried in the Federal Court. A. C. Ellis and W. Beatty of San Francisco represented Mrs. Walcott, and Messrs. Wren, Cheney, Rives and Beatty represented Watson.

The new Metal of the Present, no longer "The Metal of the Future."

GAS WORK A SPECIALTY.

MINING ENGINEERS.

EVERETTE'S MINING OFFICE.

Pioneer Mining Office of the Northwest Coast.

Having the largest permanent brick assay furnaces, chemical laboratory and mining office on the Northwest Coast, with a collection of about 400 samples of the Ores of Alaska, British Columbia, Oregon and the Northwest Territories, and having made personal examinations of nearly every mining camp on the Pacific Slope, from California to Alaska, I am prepared to do any class of legitimate and honest mining work, such as EXAMINING, ENGINEERING, SAMPLING and REPORTING ON THE VALUE OF ALL MINERAL, COAL and FIRE-CLAY PROPERTIES. BUILDING STONES, EARTHS, ASSAYS AND ANALYSIS OF ORES, WATERS, CHEMICAL SAMPLES OF ORE, PULPS, ORGANIC ANALYSIS WORK, and in fact any work connected with the office of a first-class mining geologist and chemist. Any information mining men may desire to know relative to the MINERAL OR COAL RESOURCES of the entire Pacific Northwest will be honestly given. Address **Dr. Willis E. Everette** Consulting Mining Geologist and Chemist, 1318 E Street, Tacoma, Wash.

THE LAW OF MINES

—AND—

APPLICATIONS FOR MINERAL PATENTS A SPECIALTY.

E. A. BELCHER,

Attorney-at-Law,

234 Montgomery St., San Francisco, Cal.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners' and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$5.00 post-paid. Sold by Dewey & Co., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to determination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

W. H. CONLY,

Mining, Commission.

SOLE WESTERN AGENTS FOR TYLER WIRE WORKS DOUBLE CRIMPED MINING CLOTHS.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Glove Cases, free of cost, by applying to the manufacturers.

BALDWIN LOCOMOTIVE WORKS.

ANNUAL CAPACITY 1000. ESTABLISHED 1831.

LOCOMOTIVE ENGINES!

Adapted to every variety of service, and built accurately to standard gauge and templates. Like parts of different engines of same class perfectly interchangeable.

Broad and Narrow Gauge Locomotives, Mine Locomotives by Steam or Compressed Air, Plantation Locomotives, Noiseless Motors for Street Railways, Furnace Locomotives, etc.

COMPOUND LOCOMOTIVES

BURNHAM, WILLIAMS & CO., Proprietors, Philadelphia, Pa.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and absolutely water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated. Price, \$2 each, or the entire instrument finished in gold plate, \$5.

N. W. MOODEY, Fresno, Cal.

THE GIANT POWDER COMPANY

Manufactures Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,

Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE, which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safe in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

Mining Engineers and Metallurgists

Testing and Working Silver Ores

A VALUABLE BOOK

An illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical terms, but to those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting, ore, selecting and working samples, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride of lime, etc. Under the head of "Leaching Processes" are the titles Smelting, Mexican process, Chilian process, Kroeckhke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizer, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings, and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

Price, post free, \$2.00. Sold by DEWEY & Co., Publishers, 220 Market St.

GOLD MINES

—AND—
STOCK IN MINES FOR SALE.

Dividend-paying Mines from \$150,000 up.
Undeveloped Mines from \$10,000 up.
Undeveloped Mines on Bond.
Stock in Dividend-paying Mines from \$1 up
Stock in Undeveloped Mines now being
opened from 25 cents up.

All situated in the GRASS VALLEY MINING DISTRICT, the Oldest Quartz Mining District on the Pacific Coast, and the Richest and most Permanent in the World. The mines of this district are practically inexhaustible, as nearly half a century of constant working is proof. Grass Valley has the deepest regular dividend-paying gold mines in the world, and the end is not yet, for these same mines are as rich to-day as at any time during their history.

Gold mining, especially in Grass Valley, when under honest and scientific management, is one of the safest and most profitable of all American industries. It is a business that will return annually a profit of from 100 to 300 per cent on the investment. Mining is a science acquired only by years of study, combined with practical experience. Therefore, failure is the rule whenever the management is ignorant and unscientific.

The undersigned is a practical scientific and successful miner, has made mining a life study and vocation, is honest and trustworthy, and will not, under any circumstances, recommend or deal in any but valuable paying property and properties that will develop dividend-payers.

No Wildcat Mines; no Sharp Practice; no reasonable chance for loss; Honesty and Square Dealing Guaranteed. Correspondence solicited.

Full particulars by apply to

S. B. FOWLER, Supt. Hartley Mine,
Grass Valley, Nevada Co., California.

THE BLASDEL CONCENTRATING BELT COMPANY.

We have now made arrangements to have our new Concentrating Belt manufactured in San Francisco; we can therefore fill all orders on short notice. The length and width of these belts are the same as is used on the Frue or Triumph Concentrating Machines, but can be made of any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), London, October 8, 1885.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs," for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if need be. Circulars and testimonial letters furnished on application.

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont Street, San Francisco, Cal.

(PATENTED.)

Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

Original Empire Mill and Mining Company,
Principal Office, 401 California St., cor. Sansome, S. F.
Location of Works, Grass Valley, Nevada Co., Cal.

GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1886.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:

GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID McKAY, JR.,
(Signed) Sup't North Star and Original Empire Mining Co.

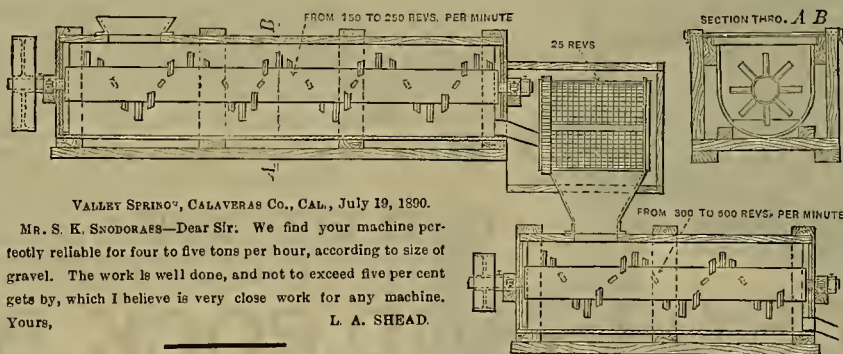

N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

COMMON SENSE PULVERIZER AND CONCENTRATOR.

This is the most successful machine yet discovered for working Gravel, Cement, Clay, etc. It avoids crushing the rocks which are washed clean and at the same time pulverizes the Cement or Clay and SAVES EVEN FLOUR GOLD.

It is only necessary to have about six inches of water to work 100 tons or over per day.

Full particulars given by addressing:

VALLEY SPRING, CALAVERAS CO., CAL., July 19, 1890.

MR. S. K. SNODGRASS—Dear Sir: We find your machine perfectly reliable for four to five tons per hour, according to size of gravel. The work is well done, and not to exceed five per cent gets by, which I believe is very close work for any machine. Yours, L. A. SHEAD.

SAN FRANCISCO, March 25, 1891.

S. K. SNODGRASS, Esq.—Dear Sir: In regard to the work done by your machine, which we have had in operation for the past three months, I can say that it has handled successfully all material as taken out of our ground, the only cement which was not perfectly broken up being an exceedingly hard cement material approaching rock in its hardness.

For all free wash and moderately hard cement it will do very good work, and must effect a great saving in working such gravels and cements, owing to the small head of water required; and furthermore, its great gold-saving qualities, as I am satisfied that fully 95 to 98 per cent of the gold freed in the machine is saved, even to flour gold, and that too without the use of quicksilver.

The automatic rejection of all rocks and material by the revolving screen makes the handling of the gravel cheaper, as all hand culling of the material is rendered unnecessary. Truly yours, W. W. B. STEVENS.

S. K. SNODGRASS, 220 Sutter Street, San Francisco.

WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS.

More than DOUBLE THE CAPACITY with One-Half Less Power and Occupying Less than One-half the Space of any other Concentrator.

Built of Best Steel and Wrought Iron.
STRONG AND DURABLE.
Price.....\$575 f. o. b.
Send for Catalogue and Testimonials

The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. This excess in length of material effectually prevents the edges from cracking; plain edge belts have to stretch about one inch to the foot as they pass around the drums. This continuous stretch cracks the edges. The improved belt obviates that difficulty.

GEO. E. WOODBURY, Man'r, 213 to 219 First St., San Francisco.

PATENTED

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.

121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS. Varying from the fraction of 1 up to 15 and 20-horse power, unequaled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

THE PELTON WATER WHEEL CO., 121-123 Main Street, San Francisco, General Western Agents.

THE U. S. GOVERNMENT BUILDING.

BUILDINGS OF THE STATE OF ILLINOIS.

Columbian Exposition Buildings.

Illustrations are given on this page of a few of the many fine buildings which are being erected in Chicago especially for use in connection with the coming World's Fair. The great buildings of the exposition will be one of its chief attractions. Their gilded domes, colossal pillars and splendid proportions will be recalled after the displays in them have been forgotten. The noblest achievements of American architecture will be arrayed around a grand court, producing an effect alike impressive and inspiring. That wealth of architectural splendor will cost something like \$12,000,000 with the attending landscape effects. By common consent, the buildings which have been designed to house the various exhibits have been termed palaces, a title which their magnificent proportions and artistic lines have fully earned. It is doubtful if such an aggregation of palatial structures has ever been gathered together within such a compass. Twelve stupendous buildings, any one of ten of which will cover more ground than the National Capitol at Washington, monuments alike to the genius of the architects as well as the progress of National architecture, fitting temples in which to celebrate the anniversary of an event of unequalled importance in the history of the Western Continent, and scores of

other magnificent edifices—such will be the World's Fair edifices at Chicago in 1893.

The United States Government Exhibition building was the first Exposition structure to be planned. It will occupy a site near the Lake Shore, south of the main lagoon and of

is classical in style, and bears a strong resemblance to the National Museum and other Government Buildings at Washington. It will cover an area of 350 by 420 feet, will be constructed of iron, brick and glass, and will cost \$400,000. Its leading architectural feature is

been pronounced by many architects second only to Richard M. Hunt's Administration Building in the magnificence of its proportions. This building will be 850x500 feet and cost \$450,000. It is located at the extreme south end of the park, midway between the shore of Lake Michigan and the west line of the park. It is just south of the Administration Building.

The building is spanned with three arched trusses, and the interior will present the appearance of three railroad train-houses side by side, surrounded on all the four exterior sides by a 50-foot gallery. In each of these long naves there is to be an elevated traveling crane for mining machinery. Steam power for this building will be supplied from a powerhouse adjoining. The two exterior sides adjoining the grand court are to be rich and palatial in appearance. The two facades of Machinery Hall on the court are rich with colonnades and other features.

The design follows classical models throughout, the details being followed from the renaissance of Seville and other Spanish towns, as being appropriate to a Columbian exposition. An arcade on the first story admits passage around the building under cover. A colonnade with a space at either end forms the length between Machinery and Agricultural halls.

The Agricultural Building is to be put up
(Continued on page 593.)

MACHINERY HALL AT THE WORLD'S COLUMBIAN EXPOSITION.

the area reserved for foreign nations and the several States, and east of the women's building and of Midway Plaisance. The Government Building was designed by Architect Win-

a central octagonal dome, 120 feet in diameter and 150 feet high, the floor of which will be kept free from exhibits.

Machinery Hall, on which Peabody & Sterns of Boston, have been working for months, has

the building under cover. A colonnade with a space at either end forms the length between Machinery and Agricultural halls.

The Agricultural Building is to be put up
(Continued on page 593.)

PRINCIPAL FACADE OF AGRICULTURAL BUILDING, WORLD'S COLUMBIAN EXPOSITION.—FROM THE ORIGINAL DRAWING.

A Lixiviation Plant.

The Construction of Details for a Modern One.

[Read by C. A. STREIFELDT, San Francisco, before the American Institute of Mining Engineers.]

A modern lixiviation-plant for the treatment of silver-ores with hyposulphite solution differs so materially from its ancestors, that a critical description of the improvements recently carried out and proposed, will not be without interest to metallurgists. While the general arrangement of such a plant depends upon local circumstances, its details of construction are more or less constant and can be described from a general standpoint.

The plant consists of wooden tanks in which the ore is treated and solutions are accumulated; apparatus for elevating and transferring solutions, and for creating a vacuum below the filters of ore-tanks; filter-presses and drying-chambers for handling precipitates; apparatus for manufacturing sodium sulphide, etc.

1. Wooden Tanks.

Construction.—Tanks should be made of clear, well-seasoned lumber. In the United States, Oregon pine is the best material for this purpose. The staves, from 3 to 4 inches thick, according to size of tank, should be ordered out to sweep of radius, and from 9 to 10 inches longer than the inside depth, but not "gained" for the bottom. The galling of the staves, 1 inch deep, is done by hand, leaving a chine of 6 inches below the bottom. In all tanks the staves stand perpendicular to the bottoms. The bottom pieces, 3 to 4 inches thick, are out to a diameter of 2 inches greater than that of the finished tank; they are grooved and joined by a tongue. All joints must be fitted with precision. White lead should never be put between the staves, but may be used in inserting the tongues between bottom pieces. The under-structures of substantial timbers, placed on a solid foundation, should be sufficiently high to allow access to the bottom in case of leakage. The bottoms rest on joists, 3 to 4 inches wide and 10 to 12 inches deep, placed about 2 feet 6 inches apart, so that the staves are left entirely free. Hoops are made of round iron, $\frac{3}{4}$ to 1 $\frac{1}{2}$ inches diameter, the threaded ends, with hexagonal nuts, passing through forged or cast-iron lugs, giving preference to the former. In order to get the full strength of the rods, the threaded ends are taken $\frac{1}{2}$ inch larger than the diameter of the rod. For tanks of larger diameter, each hoop is made in two or three sections; this is necessary to effect a more uniform closing of the stave-joints by tightening the nuts in two or three places.

After finishing, the tanks are painted on the outside, staves and bottoms, with three coats of white lead.

Dimensions.—Formerly, the dimensions of lixiviation-tanks were taken quite small: Ore-tanks not larger than 12 feet diameter and 3 to 4 feet deep; precipitating-tanks, solution-sumps and storage-tanks of corresponding dimensions. In recent works, however, ore-tanks of 16 to 20 feet diameter and 8 to 9 feet depth, precipitating-tanks, solution-sumps and storage-tanks of 12 feet diameter and 8 to 9 feet depth are put up. As can readily be seen, the care and attention required to finish a charge in an ore-tank, or to precipitate a solution in a precipitating-tank, are independent of the size of the vessel; hence, the great advantages of large sizes.

The capacity of an ore-tank for 24 hours depends upon the specific gravity of the ore, the quantity of first and second wash-water, and of stock-solutions required for treatment, but principally upon the rate of lixiviation. Capacity increases in proportion to diameter, but remains nearly stationary as far as depth is concerned; that is, the same number of ore-tanks will be required whether their depth is 9 feet or only 4 or 5 feet, in order to treat a stipulated quantity of ore per day. In fact, should the rate of lixiviation increase with reduced depth, the same number of shallow tanks would put through in 24 hours more ore than deep ones. The principal advantage of increased depth consists, therefore, only in reducing the number of charges treated.

Sluicing Tailings.—Where water is abundant, tailings are now removed by sluicing, and great depth of the charge is no disadvantage. Even where water is scarce, and tailings have to be removed by hand, deep tanks should be used. It is only necessary to provide mechanical means for moving above the tanks large buckets into which the tailings are shoveled.

Filters for Ore-Tanks.—The false bottoms for the filter, and the latter itself, are prepared as follows: Wooden slats, $\frac{1}{2}$ inches high and 1 inch wide, and separated 1 inch from each other, are fastened to the bottom. This has, so far, been done with iron screws, bedded in white lead; I would suggest pine of hard wood. The inside of the slats, next to the bottom, is cut out in many places, $\frac{3}{4}$ inch deep and 3 inches wide, so that a free passage of the solution below the filter is established. Between the ends of the slats and the staves a clear space, $\frac{1}{2}$ inches wide, is left. A strip of wood, $\frac{1}{2}$ inches high and 1 inch wide, previously cut with a saw in many places, and well soaked in water, so that it will bend easily, is now fastened round the slats, leaving an annular space, $\frac{1}{2}$ inch wide, between the strip and the staves. One thickness of stiff matting, covering the slats and the circular strip, but not the annular space, forms the foundation of the filter-cloth proper. The latter, No. 10 canvas duck, is out to a diameter 6 inches greater than

the inside of the tank, so that the ends can be pressed into the annular space described above, and kept in position by forcing down a $\frac{1}{2}$ -inch rope.

Sluice Gates.—A gate for sluicing tailings is illustrated in the *Trans.*, vol. xv., p. 359. The discharge-opening should be 18 to 20 inches wide and 8 to 9 inches high. The door is covered with a sheet of rubber, and should be suspended by a counter-weight when removed. For very large ore-tanks, say 18 to 20 feet diameter, it is desirable to have two sluice-gates diametrically opposite to each other. The bottom of the gate should be flush with the filter.

Solution Outlets for the Ore-Tanks.—These are made of 2-inch, six-ply, rubber steam-hose, which is inserted in the following way: A piece of clear plank, 3 or 4 inches thick, is fastened to the bottom of the ore-tank with wood-screws, and a hole, having the exact size of the outside diameter of the hose, is bored through the bottom and the plank, at a flat angle of about 30°. Through this hole the hose is forced. All joints are made with thick white lead, the wood screws being also bedded in this material. A pin of hard wood is finally driven through the end of the hose into the wood. If the solution-hose is permanently connected with a Montejus (see 6) for producing a vacuum below the filter, and leaching with water from below the filter is desirable, a second hose should be inserted in the bottom of the tank and connected with the water-pipe. Finally, a third outlet may be provided and connected with a Koerting ejector or a geyser-pump (see 7), if circulation of extra-solution is necessary.

Launders for Solution in front of Ore-Tanks. These launders, 6 inches wide and 8 inches deep, are made of clear $\frac{1}{2}$ -inch lumber, and painted inside and outside with asphalt varnish. They are placed level, and should be held together with properly constructed braces. Connection with precipitating-tanks is made by 3-inch, six-ply rubber hose, which is inserted in the same way as the hose in the bottom of the ore-tanks, but the hole is not bored slanting.

Launders are needed as follows: One for silver-bearing wash-water, one for waste water, one for solution, one for weak solution. If it is desirable to treat ore at different periods with cold and hot solutions, and to keep these solutions in rotation separately, a fifth launder must be added. Launders are either placed a short distance below the ore-tanks (from bottom of staves to top of launders, about 9 inches), and above the precipitating-tanks (about 6 inches from bottom of launders to top of precipitating-tank); or 5 to 6 feet above the top of precipitating-tanks, and below the upper floor round ore-tanks. The first position is taken if no artificial means are used to increase the rate of lixiviation; the second if the rate of lixiviation is increased by a Montejus with vacuum. (See 6.) The high position in the latter case is necessary to give sufficient head to the discharge through the 3-inch hose of the launder; when the solution is suddenly pressed up from the Montejus.

Boxes for Chemicals.—Solutions introduced to the ore-tanks are first conducted to a wooden box or barrel, with holes in the sides, standing on top of the charge. This prevents stirring up of the ore by a strong current of solution. These boxes also receive the copper sulphate and sodium hyposulphite for making extra solution in the ore-tank.

Tail Races.—If tailings are discharged by sluicing, proper attention should be paid to the construction of tail-races. Their inclination depends, of course, on the specific gravity and coarseness of the material; it should never be less than $\frac{1}{4}$ inch to the foot.

Precipitating-Tanks.

Stirrers.—For stirring by hand, an oar of ash; 16 feet long, is used. Mechanical stirrers are however, far superior to hand stirring. The best form of a stirrer is a propeller-screw of about 2 feet diameter, making 120 revolutions per minute. The screw revolves about 1 foot above the bottom of the tank. Since the lower end of the propeller-shaft can not be very well left without a guiding bearing, and at the same time should be protected against the corroding influence of the solution, it is enclosed in a heavy glass tube, held in position by rubber nipples and iron washers. The guiding bearing is made of lignum vitae.

Stirring solutions with air, as described in the catalogues of the Koerting Bros., is very effective. Some trials have recently been made with air stirring at the Maracó mill, but it remains to be seen whether this method decomposes sodium hyposulphite in perceptible quantities or not.

Decanting-Pipes.—The decanting of the clear solution, after precipitation, is done by a swinging two-inch gas-pipe, working through a stuffing-box. An illustration of this arrangement is found in the paper of Mr. Daggett, *Trans.*, xvi., 446. The pipe is marked there four inches, which is too large. When a propeller-stirrer is used, the pipe moving up and down cannot pass through the center of the tank, but must be shifted 18 inches away from it.

Outlet for Precipitates.—Precipitates are discharged by a two-inch asbestos-packed angle-iron, inserted close to the bottom of the tank through the staves.

Launders.—In front of the precipitating-tanks are launders, leading the decanted solution to the solution-sumps, and running de-

canted wash-water or weak solution to waste. If cold and hot solutions are kept in rotation separately, two launders must be placed in front of the silver precipitating-tanks, one leading to the sump for cold, the other to that for hot solution. The launders at the back, conveying precipitates to the storage-tanks for sulphides, wash-water precipitate and lead carbonate, should be inclined, with a fall of about 4 feet in 100 feet. These launders are constructed in the same way as those in front of the ore-tanks, but need not be so large.

Storage-Tanks for Precipitates.

These are made about 10 feet in diameter and 3 feet deep. A 2-inch rubber hose forms the outlet for precipitates through the bottom. A 1-inch decanting-pipe for solution is inserted through the staves about one foot above the bottom. Both outlets are connected with the press-tank.

Solution-Sumps and Storage-Tanks.

These should be made of the same diameter as the precipitating-tanks, but about one foot less in depth. Two of each kind should be provided, especially where solutions are heated, and hot and cold solutions are kept in rotation separately.

2. Precipitating-Tanks for Wash-Water.

If it is desirable to precipitate silver and copper from the wash-water by scrap-iron and sulphuric acid, the process is best conducted in the apparatus described and illustrated in my book, "The Lixiviation of Silver Ores," page 159.

3. Sodium-Sulphide Tanks.

The sodium-sulphide mixing-tank is made of cast-iron, 3 feet diameter and 7 feet deep. Its great depth is necessary because the concentrated lye foams considerably while adding the sulphur. The bottom is covered one inch deep with lead, to prevent its wearing out where steam is admitted for heating the lye. The two sodium-sulphide storage tanks, receiving the diluted solution, are made of 3-16 inch boiler iron, about 6 feet in diameter and 5 feet deep. All the tanks are provided with $\frac{1}{2}$ -inch asbestos-packed cocks. It may be desirable to increase the contents of sodium hyposulphite in the solution by rapid oxidation. For this purpose a gas-pipe coil, perforated by numerous small holes, is placed on the bottom of the tank and connected with an air-compressor. The air is then forced in small bubbles through the solution. Material and size of tanks for Solvay soda solution are not of importance.

4. Apparatus for Heating the Stock-Solution.

Apparatus for heating stock solution can be placed either in the solution-sumps or in the storage-tanks, depending on the most convenient location of the boilers. Coils of lead pipe, through which steam is conducted, are very effective, but, unfortunately, not sufficiently durable to warrant their cost. Although lead is not attacked by a pure hyposulphite solution, the stock-solution contains sulphates and chlorides, and these may form lead sulphate and chloride, both soluble in hyposulphite salts. Besides, we have to consider that the stock solution is never entirely free from silver and copper.

At the Maracó mill heavy cast-iron pipes one foot in diameter have been substituted for lead coils with satisfactory results regarding durability and cost.

I suggest giving to these heaters the shape of large, round, hollow disks, for a more economical utilization of steam.

Either heaters should be provided with steam-traps, or the escaping condensed water and steam should be conducted to the feed-water tank for the boilers.

(To be Continued.)

GOLD IN NEVADA.—The Belmont *Courier* says: Many discoveries of gold ore and gold dust have recently been made in various parts of the State of Nevada. The gold mines in the counties of Humboldt, Douglas, Esmeralda and White Pine are reported as looking splendid. The quartz found in the southern portion of Nye county carries considerable gold, and if capitalists take hold, the mines there will be made to yield yellow metal in good quantities. The Carson *Appeal* says the following regarding the latest discovery of gold ore made in this State: "The big strike recently made by W. Zern, in the Pine Nut district, is richer than first reported. Some of the ore has been brought down, and is filled with chunks of free gold."

The West End Oil Co. has already struck oil in the 16-inch well west of the city limits of Los Angeles, and pumping machinery is being put in. The well is only down 175 feet. If necessary, it will be sunk deeper, the company having the facilities to sink it 3000 feet. It is also reported that another well in the same vicinity is flowing 40 barrels a day.

The following directors and officers have been elected by the Homestake Mining Company: Louis T. Haggin, President; Lloyd Tevis, Vice-President; I. C. Stump, J. B. Haggin and Geo. J. Henry, Directors. The usual dividend of 10 cents per share, aggregating \$12,500, was declared payable June 25th. This is the one hundred and fifty-fifth consecutive dividend paid by this company.

Hydraulic Mining.

A Plea for an Extinct Industry.

A correspondent of the *Paeon Herald* writes as follows on the subject of the results of the hydraulic mining contest and the desirability of debris dams:—Our county papers are full of horticultural and agricultural talk, but nothing much seems to be said about mining, especially hydraulic. Without desiring to occupy much of your space, I wish to call the attention of our people to a question which it seems to me should be thoroughly agitated before the next session of Congress. Ever since the insane decision of Judge Sawyer, hydraulic mining has gradually died out, until to-day it is an extinct industry. Every one concedes that with the closing of the mines has come harder times all over the State. The effect is being felt in the cities especially. We all know and realize the fact that if the mines could again be worked, business would be better all over the State. This feeling has been growing for the past few years, since the close times incident to closing the mines have so forcibly taught the lesson. Even Governor Markham has called the attention of the President to this important subject. Yet the people whose very prosperity and happiness depend on the rehabilitation of hydraulic mining are inactive, plethoric. They all desire to see hydraulic mining resumed, and so resumed that it will not injure the farmers. That this is possible, is evident from the report of the able corps of engineers selected to make a survey and report on this question. That dams can be built to successfully restrain the debris, the engineers say is entirely practical. This the miners have always maintained, and would have accomplished years ago when they were able to, had they then been permitted to do so. They have always been willing to meet the farmers half way, and do what is just and equitable, but the farmers had the upper hand and used it without once considering the rights of their fellow citizens, the miners. Had the miners been traitors to the government, had they been attempting to destroy our institutions and steal from the people their liberties, they could have been treated no worse by the farmers. Through the leadership of a few fanatics, the farmers were led to regard the miners as outlaws who intended the destruction of their property. They fought the miners bitterly, they conceded them no rights, they never thought of the ruin, desolation, and misery the accomplishment of their ends entailed on one of the fairest portions of our State. We might expect such action from a semi-barbarous nation bent on conquering and destroying another, but for the citizens of one portion of a State, who love the same flag, who cherish the same traditions, who believe in the same principles of truth, justice and the equal rights of man, is deplorable indeed. Especially is this true when a different and more equitable solution was attainable.

Little did the founders of our constitution dream when they inserted in the preamble of our constitution, the phrase, "to establish justice, and to secure the blessings of liberty to ourselves and posterity," that the time would come so soon in the history of the government, that that very government itself would become the instrument of denying justice and liberty to a section of country larger than four of the States which then formed part of the original thirteen. Little did they think that that very government would be the means of inflicting a greater wrong on a portion of its people, than many for which they fought England twice, and on a class of its citizens too, than whom none were more generous, open hearted or liberty loving; than whom none had done more to sustain that very government in its hour of peril and need, simply because the miners, engaged in an industry for the purpose of gaining a living, which to a certain extent conflicted with and injured a small portion of the State, which injury they had not intended, and which they were willing to do all they could to avoid, they were prosecuted, by means of the very government which they dearly loved, which they had stoutly defended and generously maintained. Spies were sent among them to watch them, for what purpose? To ascertain whether they were plotting and scheming against the rights of others, whether they were endeavoring to destroy the government? Oh no! only to see whether they were earning a living, that they might support their families and rear their sons and daughters that they might become good American citizens. And because they did this, the government which had sold them their property was used as the means of denying them this right, and so of despoiling their homes, destroying their property and inflicting unold misery upon them. And if they insisted on earning a living they were cast into prison. Was a greater injustice ever done to a quiet, peaceful class of American citizens? This is not overdrawn, for I have seen men who fought to preserve the Union, who shed their blood for its defense, have their property which it had taken 20 years of toil to develop or accumulate, rendered valueless. I have seen them go to their graves, poverty stricken and bowed down by the rank injustice done them, without giving them even a fair trial. I have seen happy homes broken up, and the members scattered to the four winds like the Acadians in 1755. Of course they were not compelled to go at the point of the bayonet, but starvation is as effective as the

sword. I have seen men once prosperous and happy, driven insane, by the sudden change to penury. I can see about me to-day old men and women, who began in youth, when no thoughts of injunctions or imprisonment menaced them, if they wished to mine, to toil and accumulate mining property, expecting that it would support them in old age, I can see them to-day toiling, striving for a mere existence, because their property is of no value.

I believe these are all unnecessary, and for that I believe the folly of the farmers approaches a crime. Had they been reasonable, and had they given the propositions of the miners a fair trial, the mines might be running to-day and all this ruin and misery averted. It is not yet too late to try dams. It has been proven to be feasible. The commissioners report it so, but they say the miners should build the dams. This is unreasonable because hydraulic mining property is of no value, capital has been driven away from it and other kinds of mining can go on without dams. The Government owes it to the miners to build these dams for them. The Government sold them the property in good faith, and then it said they could not use it, so made the property valueless, and consequently the miners are not able to build the dams. If the Government can afford to pay \$300,000 for the lives of a few Mongolians, or if it could afford \$7,000,000 for Alaska, certainly it can afford even a million of dollars to make reparation for the injury it has inflicted on a large portion of one of its most promising States. This question should be agitated. The miners should organize and see that their claims are presented to Congress, that their rights be given which belong to them. If the Government sanctions and assists in building dams, certainly such an insane decree as Judge Sawyer's cannot be enforced. Let us demand our rights and strive to obtain them. Let the farmers join with the miners in giving the dams a fair trial, then if unsuccessful let them close the mines and have the government indemnify the miners for their property.

A Four Months Prospect.

The *White Pine News* says: B. B. Bird and Sam Snyder of Taylor arrived here Wednesday from a four months prospecting tour to the southern country. They left Taylor last January well equipped for the tour, and proceeded south by way of Pioche, down Pabranagat Valley, diverging west to the Pah Rump country; thence west to Death Valley. They were at Camp Montgomery and the much talked of Breyfogle mine. That country they represent as very tough for both man and beast, water being very scarce, and what little there is of a bad quality. They tell us that the long looked-for Breyfogle mine has been found, and that all it yielded its second discoverer was about \$500, which he took out in a few days, when the mine "pettered." Sometimes they traveled from 200 to 300 miles through the country without seeing a human face. From Death Valley they steered west through southern Inyo county to Mohave, Cal. Here they changed their course, traveling north until they reached the head waters of Kern river, where Mr. Bird had mined many years ago, and where he still believes there are paying placers as well as ledges. He found, however, but very few men mining in that country and the mines stood just as he had left them twenty years ago. It was not until the return trip that any sign of winter weather was encountered, when they experienced a good deal of rain and badly washed roads. Messrs Bird and Snyder traveled over 1,200 miles, and they say that in all that country they have seen and prospected, none of it compares favorably either as a mineral or agricultural country with White Pine county. So they came back to pitch their tent for good.

THE ANACONDA CO.—The *Engineering and Mining Journal* says: We are reliably informed that the great Anaconda sale is going through. The debenture and preference shares have all been "underwritten," and only the £1,000,000 of common stock is to be put on the market simultaneously in London, Paris, Berlin and New York. The Anaconda matte in England is all sold, 5000 tons about two weeks ago on a basis G. M. B. and G. M. O. over three months, and the other 5000 tons a week ago; delivery extending over a year on the same basis. As the remainder of the stock is held by friends of the new Anaconda Co., and the mine is shut down, the market price of copper must improve. The prospectus is ready, but it may be September before the money market looks sufficiently auspicious to launch the new concern. The recent drop in copper on the Exchange in London was due to the belief that the object of Mr. Livermore's visit to Europe was to place a large line of Lake. There seems to be a very erroneous impression abroad about the stocks of copper in the United States. They are, in fact, lighter than on the first of the year, and are not likely to increase. The outlook for copper appears to us to be good, and higher prices may rule at no distant date.

THERE are 16 gas wells in active operation in Stockton, and the supply seems to increase rather than diminish. It is copied at 25 cents a thousand feet, and for manufacturing purposes nothing can beat it. It has given a great impetus to manufacturing, and the result is that Stockton has a great boom.

Electrical Chlorination.

The first practical demonstration of the extraction of gold by means of chlorine, is due to the late Professor Plattner, upon whose discovery all subsequent improvements are based. The most noteworthy modifications and improvements are those of Calvert, Jackson and Ott, Mears, Deeken, Patra, Reesner, Henck, Newberry and others of less note. The introduction of electricity in the extraction of gold is of more recent date, and the leading names of those who first adopted this method are Plober, Ansel and Marle, and Cassel. The latter patent was approved by capable authorities, but although five years have now passed, Cassel's process has not forged its way to the front.

Mr. Th. Ranft, M.E., of Sydney, says the *Australian Mining Standard*, now introduces an electric-chlorination process, in which he claims to have overcome the vital defects before experienced in electrical chlorination, viz., the getting rid of the sequent hydrogen and sodium as they are formed by the electric current when passing through the electrolyte. In all processes where the hydrogen cannot be kept separate from the chlorine gas, the two will combine and form hydrochloric acid, which combination does not solve gold and is in every way most injurious to the process. The inventor does not claim or patent any new law, but an apparatus by means of which the laws observed are complied with. The apparatus consists of two cylinders, one within the other. The inner cylinder, made of a porous material, serves four functions, viz., 1st, as a filter, 2d, as the negative pole or cathode; 3d, it acts as a burr to allow the precipitated gold to escape along with the caustic soda, and lastly it allows the formed hydrogen gas to escape at the top. The outer cylinder, which is air tight (except at the places where it is required periodically to discharge) serves three purposes; firstly, it forms the positive pole or anode of the battery; next, it acts as a chlorine gas generator and store, and lastly, as the chlorinating vessel.

The process performed in the apparatus is as follows: The ore to be treated (free of sulphur, arsenic, lead, zinc or bismuth) is mixed in certain proportions with common salt. It is then fed into the outer chamber, where the anode is, and the electric currents enter. Water is then added, which dissolves the salt in the ore, and this combined with the saline liquor, forms the electrolyte. An electric current from a dynamo it then led into it by the anode, and passing through the solution into the inner chamber or cathode, is discharged back to the dynamo. The chemical actions produced by the passage of the electricity is to decompose the electrolyte into its elements. Hydrogen and oxygen are the products of water, chlorine and sodium those of salt. Hydrogen, being a positive substance, deposits on the negative pole; oxygen, on the other hand, being negative, deposits on the positive pole. Chlorine and sodium deposit respectively on the positive and negative poles. In order to prevent the accumulation of oxygen and hydrogen, contrivances are provided, which continually wash the surfaces of the anodes to prevent polarization, which would stop the whole process. With regard to chlorine, it has been established by Begerel that chlorine in its nascent state is more active than afterward, so that if in the ore under treatment any gold is present, it would now be almost readily attacked by the chlorine and form itself into chloride of gold (salt of gold) which again is soluble in water.

The gold being now in solution is readily acted upon by the electric current. The molecules, as established by Grothus, 1805, are under the same condition as any other molecules, which in their transit to the negative zone become split up into their elements, the chlorine parting and returning to the positive zone, while the gold is deposited on the negative pole in a fine metallic condition in the inner chamber. From this it is washed and drawn off in the contracted part of the inner chamber, in conjunction with the caustic soda, and passed through a filter. The powder is then calcined, and the gold remasses.

The gold having been extracted from the ore, the latter is drawn off at the bottom of the outer cell, and an equal amount entering simultaneously at the top from a hopper, in which it has been mixed with the salt, makes the action continuous. In a working plant, every ton of ore will be virtually from 20 to 24 hours under the chlorinating and electrical influence, and travel about 20 feet, which will give sufficient time for effective treatment.

As to the cost, it is estimated to be about one-ninth of the present cost of chlorination, or that three shillings five pence per ton should cover the cost of supervision and sinking fund for capital. The inventor estimates the outlay for a complete plant to be £250, exclusive of an engine to drive the dynamo.

A NEW HIGH EXPLOSIVE.—The ordnance experts have been invited to test another high explosive, the inventors of which claim for it all the desired qualities, that is, perfect safety in handling it by yourself and exterminating destructiveness on your enemy. The explosive in the present instance has the patriotic name of Americanite, and is manufactured over in Virginia. Americanite is said to be capable of explosion by a gunpowder fuse, when strongly confined, and can be detonated without the use of a fulminate, a feature of peculiar value for ordnance purposes.

Free Coinage of Silver.

The fight now on for free coinage is nothing more than a fight between capital and labor. Labor is demanding free coinage, which is inimical to capital, and is as much an irrepressible conflict as was that between freedom and slavery.

The Grange has demanded the free coinage of silver through its representatives in the National Grange. All farmer and labor organizations of any importance have demanded free coinage, and yet with all the resolutions and demands that labor could make on the present Congress, the bill for free coinage was defeated. The same crowd of financial wreckers that were instrumental in having silver demonetized in 1873-74 are to-day fighting free coinage.

In demanding free coinage, labor is asking for but very little more than the restoration of silver to the position it occupied before. The bill for the demonetization of silver was sneaked through Congress by men who, if they had their just deserts, would be spending their time in a State prison instead of in Congress, where some of them are to-day still the champions of organized capital.

The opponents of free coinage are working and depending upon the forgetfulness and ignorance of the people to carry their point.

The chief arguments of capitalists and their willing tools in Congress are, that free coinage will drive gold out of the country; the same argument was used prior to the Act of Feb. 28, 1887, as an inevitable result of a limited coinage of silver of \$20,000,000 per month.

Pass that bill said the gold bugs of Wall street, and you will drive gold out of the country; they are raising the same cry now. But did it drive gold out, as they were sure it would?

No; but instead of having \$167,000,000 of gold coinage in the U. S., it has increased until we now have \$662,000,000.

That is how limited coinage drove gold out of the country from 1887 to '90. What reason have the anti-coinage men to base their predictions on only the forgetfulness or ignorance of the people? History has proven them to be false prophets and they should be stoned out of their position by the ballots of an outraged people.

We tried free coinage in this country for more than 80 years from 1792 to 1873. We had free coinage and found it a safe financial policy. Upon that policy we built a great and prosperous nation and carried on one of the greatest wars in modern times; all industries grew together, each one retaining a just reward for its labor; the equilibrium of each industry was maintained, strikes among laborers practically unknown, trusts and combinations to oppress were wholly unknown.

But there is another objection brought against free coinage equally as absurd, and when investigated shows that the authors of the objections are either ignorant of the facts or else they take the people to be fools.

Wall street money bags, etc., are predicting a terrible calamity in shape of an influx of foreign silver, should free coinage be adopted.

France has 3,250,000,000 francs in silver, which is worth in her jurisdiction \$644,695,000 in gold, 15.50 to 1.

Suppose America should adopt free coinage and France should want to wreak vengeance upon us by sending her silver here and flooding our markets, as some would-be statesmen would try to make us believe, how would she succeed?

We said she had 3,250,000,000 francs; if sent here and coined at our mints at our ratio of 15.50 to 1 here, 3,250,000,000 would be worth \$627,250,000, a clear loss to her of nearly \$20,000,000.

Spain, Belgium, Italy and Switzerland, which coin at the same ratio, would sustain corresponding losses on their silver.

India coins at 15 to 1, has stock of silver worth at home \$1,352,000,000, and worth at our ratio \$1,269,000,000, will she flood us with cheap silver and lose by so doing \$83,000,000? That would be a money-making scheme throughout. Where are those large importations of silver to come from that threaten to engulf us? Only from the imaginative brain of Wall street tools.

The chief among them stands John Sherman who seems to have been the leader in smuggling through Congress the infamous bill, which practically etopped the coinage of silver; and when in '87 the limited coinage act was passed, Sherman advised President Hayes to veto the bill, 'tis said. Sherman is said to be a great financier, but his financiering has always been in the interest of Wall street as against the people; and in the fight now for free coinage he is as true to Wall street as the needle to the pole. But, says Wall street, a silver dollar is only worth 72 cents. Admitting that, it is only technically so and has been made so by restrictions placed upon it; remove the restrictions and the silver dollar will be all right. What does the farmer or laboring man care for technicalities, so a silver dollar will buy 100 cents worth of produce or pay 100 cents worth of debts. The truth of the matter is, the laboring classes would be thankful if they only had plenty of good, old, silver dollars, and they propose to have them.

The people are aroused upon this money question and are beginning to see through the hellish schemes of Wall street money sharks, who were instrumental in destroying the greenback and saddling millions upon millions of dollars of debts upon the people for labor to pay. Not con-

tent with the destruction of the peoples money, they demonetize silver (by a dirty trick) thereby destroying millions of dollars of property at one fell swoop, bringing bankruptcy and ruin on thousands of innocent men and women; and when people demand relief by free coinage the plant tools of Wall street say, 'twill drive out gold, 'twill flood us with silver from other nations, etc. Pah! Let her flood.—*Am. Grange Bulletin.*

Spoiling a Mining Deal.

The *Idaho Avalanche* says: Quite an important mining deal was on the eve of being closed here a few days ago, which would, in all probability, have increased the output of bullion and the business of the camp very materially, but just on the eve of the consummation of the trade, a man who had an old grudge against some of the parties in the deal, got to the ear of one of the purchasers, and, by telling what many here know to be most willful falsehood, stopped, or at least delayed, the deal. The man who did this is trying to dispose of a mining property himself, and when parties come to inquire into its merits, the other fellow will have his revenge, and will bring every influence he can bear to prevent a trade. Thus matters go in this camp, and thus they have been going for many years. Many of the people have been here so long, and this practice of venting personal malice has been so long in vogue, that there is scarcely a property owner in the camp wishing to make a sale, who will not find some one ready to give the property a bad name. We have known of several recent instances of capital being frightened away from here by this out-each-other's-throat idiosyncrasy. Any man with a grain of sense ought to see that mining is in no way a competing industry, and every disparaging remark about a neighboring property, indirectly injures the entire industry. The owners of the De Lamar mines would be in no way the losers if any of the adjoining properties should turn out to be even greater than theirs. If A succeeds in disposing of his property, his neighbor B stands all the better show of finding a customer for his, provided A has not swindled the purchaser. But here, if A finds a buyer, B will try to spoil the deal by saying disparaging things about A's property, in the hope that the buyer can be induced to take his instead. By this means the buyer is frightened away and neither make a sale. It is time to stop this kind of idiotic procedure. This country is full of good mining properties, the greater number of which belong to persons who have not means enough to develop or work them. The majority of such owners are willing to sell at reasonable prices, and no one of them ever improves his chances by preventing the sale of his neighbor's property.

The State Fair.

We can but remind our readers that an important matter in connection with the State Fair at Sacramento is the liberal premiums offered now as farm produce premiums. There is no doubt these individual premiums will be an incentive to farmers all over the State to join in making their county exhibits, and have their products in the county exhibit for a premium, and also an individual premium "for the most extensive and varied exhibit of farm produce grown by one person or firm;" first premium, \$350; second, \$150. It is hoped that liberal premiums offered for farm produce will induce producers throughout the State to take advantage of it, and make this fair notable in the lines of farm produce, uniting the products of the State with the blooded stock of the State. The management has this year decided upon a new feature, and that is to increase the race meeting from nine to eleven days, six trotting and five running. The increase from a nine days' to an eleven days' meeting will be watched with much interest. Purse and stakes aggregating nearly \$50,000 will be offered in that time.

There seems to be a wide disposition to make the State Fair to be held this year one of the most successful in the history of our State. The extra appropriation made by the last Legislature, and the liberal premiums offered the counties and individuals for farm exhibits, meet with wide commendation. A Press reporter called on Secretary Edwin F. Smith last week, and learned that there had been more applications by exhibitors up to date than for any previous year.

He noticed a full force of men working on the pavilion, renovating and putting it in shape for the coming fair. In anticipation of a large following this year, the Board of Directors have concluded to make several additional improvements, and the prospective success will warrant some additional attractions for those who wish to spend a holiday at the coming fair.

FREE COINAGE.—The meeting of the Free Coinage Silver Committee, which was to have been held in Washington, on the 18th, will be held at New York instead. The proposition for a compromise on the coinage of products of American mines is not regarded favorably by the committee, who want free coinage in the fullest sense of the term. Senator Stewart said to a reporter to-day that he was confident that a free coinage bill could be passed through the next Congress and over the President's veto.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

BAY STATE.—Cor. *Amador Ledger*, June 13: The picnic at the Bay State mine on Thursday last passed off in the most pleasant manner. The ceremony of naming the mine was performed in grand style. At the appointed time two fair shareholders, Miss Carrie Easton and Miss Belle Summers stepped forward. One of them seizing a pick plied it with right good will, until quite a lot of rock and dirt were loosened up, when the other young lady threw out the dirt. After working in this way until they had formed the mouth of the new shaft that is to be, they retired from their labors and the ceremony of baptizing the mine and giving it a name was done by Miss Geneva Jones, daughter of W. T. Jones, by naming it the Bay State Mining and Milling Company, Limited, and breaking a bottle of champagne over the point of a pick. Hon. John A. Eagon delivered a very interesting discourse over the great wealth of this section as a gold-producing part of the county. Mr. Parks of the Kennedy mine gave the location a very careful examination and seemed to have a very favorable opinion of the property, which gives great courage to the shareholders, as Mr. Parks is known as one of the most successful miners in the State and has been instrumental in making the Kennedy mine one of the best dividend paying mines in the State. W. T. Jones is another of the directors of the Bay State Co., and is well known throughout the State as a successful miner, foreman and present superintendent of the Plymouth Consolidated, a man that never owned a foot of mining ground in the county before, but is at present interested in the Bay State to about 34,000 shares, and expresses great confidence in the outcome. Arthur Young, another director from Placerville was well pleased with the location. There was also present directors W. A. Green, L. G. Norris, A. J. Crain, Mr. Brown, superintendent of the Great Eastern, and a very successful mine boss in Nevada, Arizona, and California, also Morris Brinn of Sutter Creek, who has had large experience on the mining belt. Thos. Morris, an old mine foreman and miner in this State and Pennsylvania, and hosts of miners from all parts of the county. The general verdict is that the location and present prospects are good. The rock yielded \$3.74 at 50 feet deep, and getting better as it went deeper. The sinking will be made in the foot wall, to avoid water, and a crosscut will be run at 300 feet deep, when it is expected that the rock will go \$8 per ton. The estimate is that it will take about eight months to sink and crosscut the ledge.

KENNEDY.—*Amador Ledger*, June 13: Mr. Barton, the president of the company, also Mr. Judson and F. Reichling came up Sunday evening on business pertaining to the mine. One of the reasons of their visit was in relation to the sulphur works. The sulphur, while carrying a large percentage of gold, are heavily charged with arsenic, which renders the smoke and fumes very obnoxious. The fine that is designed to carry off the smoke is defective, and the smoke consequently is troublesome to persons in the vicinity. It is the intention to thoroughly remedy the evil either by building a regular brick flues to the top of the hill to carry the fumes high enough to obviate the difficulty or by some other effectual method. Everything in connection with the mine is looking well. Sinking operations at the south shaft are progressing favorably. The ore body on the lowest level is opening up grandly, and is as far above the rock encountered in the level above, as that level was an improvement upon its predecessor. If in sinking another 100 feet the improvement in quality and size of the ledge should continue, and there is every reason to believe it will—it will insure a career of prosperity for this leading mine of Amador Co. for many years to come.

NORTH STAR IMPROVEMENT CO.—At the annual meeting of the North Star Improvement Co. the financial statement for the past year ending June 1st, 1891, was presented. The shaft was sunk 128 feet (making a total sinking of 1030 feet) with 599 feet of drifts and crosscuts. All developments so far have given the company but little encouragement. Indications show better at 600-foot level, south. Therefore the directors decided to obtain a lease of the adjoining claim, Comet, south, and continue explorations south at 600-foot level. Also obtained new agreement, with original North Star owners for an extension for five years, to June 1st, 1895. The company became endowed with new life and vigor, still hopeful of meeting success. The old board of directors was re-elected as follows: E. C. Voorheis, president; H. H. Towns, treasurer; R. C. Downs, H. Rees, J. L. Mayon, secretary.

El Dorado.

ROLLER MILL.—*Georgetown Gazette*, June 11: The Centrifugal roller mill at the Sailor Jack mine was put in operation on the 21st of May and has been grinding 12 hours a day since that time. County Clerk Bosquit informs us that everything is working nicely and that the mill is a great success on the soft rock now being taken from the mine. A Woodbury concentrator is also in operation and has saved about a ton of sulphurets from the ore. Ten tons of quartz are being crushed every 12 hours.

GRAVEL CLAIM.—*Mt. Democrat*, June 13: Johnny Davey, who recently purchased an interest in the Larsen gravel claim, near the Six Mile House was in town during the week, and seems to be well satisfied with his bargain. He had with him a medium-sized vial filled with coarse gold, the pieces varying in size, and valued at \$65, which was sufficient evidence that he has good reason to be pleased with his purchase.

Inyo.

SALINE.—*Register*, June 11: J. H. Stoutenborough came up from Saline valley a few days ago. Works, equal in size to those of Conn & Trudo, are being put up, on the north side of the marsh, about four miles from Conn & Trudo's. With Mr. S. are interested Messrs. Roberts, Brockman, Lent and Millner. Though that country is barren and hot, good water is obtained within a few feet of the surface, and wood is conveniently near.

Nevada.

WEST HARMONY GRAVEL MINE.—*Herald*, June 10: The West Harmony gravel mine is a busy place now. The work of development, both above ground and below, is being pushed as fast as men and money can do it. The incline is now down about 270 feet. It is a two-compartment shaft and is in hard blasting ground. It is a fine shaft. The hoisting works is as fine a building as was ever erected over a mine. It was put up to stay and is built in a most substantial manner. Steam-power is being used for hoisting at present, but the frame for a large Pelton water-wheel is being set up and as soon as the South Yuba Co.'s new ditch is completed water-power will be used. The West Harmony people propose to crush their gravel, and a mill will be built on the west side of the hoisting works. The mine is situated on a very steep hillside and the company has paid out a great deal for the construction and repairing of roads. They have spent considerable in repairing the county's road up that way, also. Hon. B. J. Watson is personally superintending the work and he may well feel proud of it.

PEABODY MINE.—*Grass Valley Union*, June 12: The new shaft in the Peabody mine has reached the lower level run from the old shaft and is now being continued down on the vein into new ground. The new shaft strikes the vein on the pay shoot, which yields fine milling ore. The vein is several feet in width. As the shaft is sunk the water will be pumped up to the present lower level and run to the sump at the bottom of the old shaft and from thence pumped to the surface by water-power. A 10-inch pump will be used in the new shaft, which is expected to be of sufficient capacity to handle all the water that will be encountered for some time to come.

CALIFORNIA MINE.—*Grass Valley Union*, June 17: The vein in the north drift of the California mine (Deadman's Flat) is now showing a width from 12 to 15 inches. The quartz is a ribbon rock, bandstone in appearance, and is showing well in free gold. The point at which this rock is found is 70 feet deeper than any previous working done in the mine. The prospects for the California may well be considered as very encouraging.

WASHINGTON.—*Nevada Transcript*, June 11: At the Washington mine, Ormonde, for the last 20 feet the 400 level has been in a chute of ore from three to four feet wide yielding at the rate of \$80 per ton. As the drift has advanced the chute has steadily improved.

CENTENNIAL DRIFT.—*Tidings*, June 12: It has been about conclusively established that the latest strike of gravel in the Centennial drift mine, this county, is of the genuine blue gravel lead. The gravel will pay handsomely. Comstock parties own the Centennial and have spent considerable money on it.

Plumas.

NEW MANAGER.—*Greenville Bulletin*, June 10: The Little Jamison mine has a new manager, Mr. Cheney, who will push development work as fast as possible. Much will be done at this mine this summer in the way of development and improvements. The prospects of the mine are very flattering. Reports have been in circulation that the Plumas Eureka has been discharging men, thus reducing their force. Mr. Cornell informs us that the report is a mistake; that, on the contrary about 20 more hands have been employed during the past ten days. Very flattering results are reported from the mine owned by Supervisor Thompson, situated near Quincy. The work of sinking the shaft in the Crescent mine continues, and with good success. The progress made is as good as can be expected. Abe Bunnell informs the *Bulletin* that the mining outlook on the North Fork, is much better this year than last, and that considerable money is being taken out. The owners of the Shenandoah mine, at French Ravine are pushing work this spring. A ten-stamp mill will be erected as soon as possible. In development work and the necessary preparations for the crushing of ore, considerable money will be spent this summer.

San Diego.

THE SILVER STRIKE.—*Julian Sentinel*, June 11: Several parties who left for the desert last week have returned and others are on the way. They come straggling in tired, hungry and disgusted. Some brought samples of the ore and had them assayed at Stonewall, but did not get satisfactory results. The latest reports are not very encouraging to say the least.

STILL ANOTHER.—For the past two weeks reports of a rich gold strike somewhere between San Bernardino and Julian have been floating around in the air. The new mine was discovered some two weeks ago by S. A. Sniffen and is owned by W. P. Meredith, Chas. McLoyd, S. A. Sniffen and Wm. Johnson. It has been named the Mountain Queen and is situated about three miles north of the Agua Caliente, some 25 miles north of Julian. Several promising locations have been made by the discoverers and several parties are now prospecting in the neighborhood. The quality of the quartz is entirely different from anything ever seen in this locality and shows free gold in quantities that are not often seen. When the discovery was first made 2½ pounds of the ore was sent to San Diego and a \$5 button was the result. This put the owners, who are poor men, on their mettle, and they at once decided to take out a few tons and have it milled here, this being the nearest point, to ascertain its exact milling value before creating any stir about it. This they have done, the ore having been milled last Sunday by W. O. Havermale. The cleanup showed \$160 for the four tons, or \$40 per ton. The ledge is about a foot in width and the gentlemen have only sunk a prospect hole a few feet. The surrounding territory has been prospected but little, but we are informed that the mineral belt is quite extensive. This find only confirms our oft-repeated assertion that the work of the prospector is by no means finished in this mountain country.

Sierra.

THISTLE.—*Mt. Messenger*, June 13: The prospect drift at the bottom of the Thistle shaft is said to be some six or eight feet above the bedrock, but will immediately be sunk deeper to thoroughly prospect the ground.

GRAVEL.—Supt. Meikle commenced to take out gravel for the new large dump at the Battle Mountain Ex. new tunnel, last Monday, and will begin washing it on completion of the reservoir, near mouth of the tunnel early next week.

TUNNEL.—Arrangements have been effected whereby a tunnel will be driven from the Ante Up

claim in Woodruff creek to tap the Brush creek quartz ledge, which was so rich when worked years ago.

Siskiyou.

SHAFT SINKING.—*Yreka Journal*, June 11: The Yreka Blue Gravel M. Co. has set men to work sinking a double-compartment shaft, 477 feet, at the Horace Knight ranch, now owned by T. D. Burrows, on the Oberlin road, about a mile south of Yreka. It is started about 100 yards north of the wagon-road and will be timbered. So soon as the shaft is low enough down, day and night shifts will be put to work so as to reach gravel as soon as possible. This, it is thought, may be done at a depth of 100 feet or so. Should water interfere with the working, a first-class pump will be brought into service. When the blue gravel is struck side tunnels will be run in from Yreka creek. The company think they have commenced at the right place to reach the main blue gravel channel running through Siskiyou county. Chas. Jordan, an experienced miner, is to superintend the work.

QUICKSILVER.—*Siskiyou Telegram*, June 11: I have it from good authority that there is to be a wagon road built from somewhere near Cole's station to the quicksilver mines on Beaver creek; that the company will put up furnaces at the mine, besides numerous other improvements. The road will open up quite a mining camp, and a large amount of valuable timber land; also good mineral springs. There is already a crowd of men working in the quicksilver mine, and they are undoubtedly good miners if properly worked.

Trinity.

CANON CREEK MINES.—*Trinity Journal*, June 13: The mines on Canon Creek are looking as well as usual and the output of hulkion is as good as it has been at any time since the camp started. The Chloride Mining Co., have struck their ledge in tunnel No. 2, which they have been running to tap the ledge at a greater depth, and the ore looks very well. It is about a two foot vein and of good grade and shows indications of going down to a great depth. As soon as the mine is well open on this level another tunnel will be started to tap the ledge 100 feet deeper. The Bailey Co. is getting out rock to be crushed at Chloride mill in order to get a good mill test of the ore; they will probably have 100 tons or more crushed. They are now drifting on the ledge and it bids fair to give them a handsome profit on the crushing. The Buck's Ranch Co., have their mill shut down for a few days while they make some changes in the track from the mine to the mill. Their ledge looks about as usual, so we are informed. Mr. Shattuck has put in an amalgamating pan that will save much of the fine gold that they think they have been losing. W. J. Grigsby informs us that he has discovered another ledge a little above and south of Little East Fork. He says it is about a foot vein and is high-grade rock.

NEVADA

Washoe District.

BEST.—*Virginia Enterprise*, June 13: An entirely new find in this mine is making the new owners feel comfortable in their venture.

YELLOW JACKET.—Shipping 100 tons of gold-bearing rock daily to the Santiago mill, and about 40 tons of mixed ore to the Brunswick. The gold rock assays about \$7 a ton, and the gold and silver ore about \$18 a ton.

JUSTICE.—There has been no work done in the face of the 822 level north drift since last report, as the time has been occupied in putting in a chute and timbering the north winze where the connection was made with the drift. Are stopping ore of fair quality 30 feet back from face of north drift. The 675 and 722 stopes on the south end of the mine are looking well. Shipped 167 tons and 585 pounds of ore to the mill, worth \$23.89 a ton as per battery assays.

SEG. BELCHER.—On the 600 level the west crosscut from the south lateral drift is out 120 feet. The face is in a mixture of soft porphyry and clay.

KENTUCK CON.—The south lateral drift from the 1000 level east raise was advanced 13 feet; face in low-grade quartz on the average but containing spots of ore. The raise from the north crosscut on this level has been advanced seven feet, and is up 63 feet above the track floor; top in low-grade quartz. The raise from the south lateral drift on the 950 level is up 15 feet; top is in low-grade quartz containing occasional bunches of ore.

CHALLENGE CON.—The joint Confidence and Challenge west crosscut on the 200 level is out 12 feet, having been started during the week; the face shows quartz. Joint Confidence and Challenge east crosscut from the north drift on the 1100 level is out 22 feet, having been commenced during the week; the face is in porphyry. Joint Confidence and Challenge east crosscut on the 1000 level is out 12 feet, having been commenced during the week; face shows porphyry.

CON. IMPERIAL.—We are still following up and taking out small streaks of ore on the upper levels and prospecting in and around the old stopes, where we find some fillings and bunches of ore of fair grade.

CROWN POINT.—The east crosscut from the south end of the 350 stope on the eighth floor has been stopped. Have started the main south lateral drift which has been run on the 300 level to and connected with the 400 raise. It is out 12 feet and the face is in porphyry. Are engaged in cleaning and repairing the 500 west crosscut preparatory to resuming work there. The east crosscut from the 1000 level, south lateral drift has been extended 13 feet since last report, and is now out a total distance of 162 feet. The face is in porphyry.

BELCHER.—Have started a west crosscut from the south drift from No. 2 crosscut, 200 level, equal to a distance of about 160 feet from the shaft. It is in 12 feet and the face is in a mixture of porphyry, clay and quartz of low grade. The north drift from the main west crosscut from the shaft, has been extended 33 feet and is out a total distance of 51 feet; face is in a mixture of low-grade quartz and porphyry. The east crosscut from the north lateral drift on the 1500 level was extended 17 feet during the week, and is out 55 feet; face is in low-grade quartz, mixed with porphyry.

SAVAGE.—Milled 570 tons of ore of the average battery assay of \$17.25. We have haulion on hand amounting to \$7,000. The E-street tunnel has been repaired and advanced 50 feet since last report, making a total distance of 700 feet. The west drift

from the new station of the Potosi tunnel level has been extended 22 feet, making its total 95 feet from the shaft. On the 750 level they are extracting ore of good quality. On the 750 level the south upraise has been carried up 73 feet. They are saving some ore from this upraise. On the 1100 level the north drift from Hale & Norcross side was advanced 15 feet, making the total distance 135 feet from south boundary. This drift is in a solid body of clean quartz, but not quite good enough to save or pay. On the 1400 level have resumed work in the face of the main north drift and have advanced the same 22 feet; face in quartz and porphyry. The east winze from this level is down 19 feet; bottom in low-grade quartz.

HALE & NORCROSS.—On the 1400 level the north winze from No. 3 east crosscut is down 155 feet, to the 1500 level. The joint winze in No. 5 east crosscut on our south boundary has been extended 15 feet, making its total 40 feet. On the 1500 level the north lateral drift was advanced 35 feet, making total distance from the station 85 feet. This drift will soon be connected with the south winze from the 1400 level and will then be able to crosscut and thoroughly prospect this level. The bottom is most all in quartz giving low assays. The south lateral drift from the station on this level was advanced 25 feet; total depth, 65 feet. Face in quartz and porphyry. Have resumed work in the main incline below the 1500 station. Have retimbered the same 25 feet below this level.

UTAH.—Incline winze has been sunk 25 feet; total depth, 155 feet, continuing in porphyry, clay and quartz. At a point in the winze 140 feet down are cutting out a station.

SIERRA NEVADA.—Have repaired the Kenosha tunnel a distance of 130 feet. The west crosscut on the 650 level from the northwest drift, 571 feet from the shaft, is out 515 feet, 38 feet having been made the past week.

OCCIDENTAL.—Extracted pay ore from the stopes in the 350, 400 and 450 levels. North drift from No. 1 upraise, 500 level is in 123 feet, face in quartz and porphyry. The south drift from same point is in 97 feet; face in hard quartz giving low assays. The upraise from the south drift, 600 level, has been connected with the main tunnel on the 550 level. Have started a winze in fair ore from the south drift on the 600 level at a point 100 feet south of No. 1 winze. East crosscut from the north drift, 650 level, at a point 150 feet south of north line, is in 17 feet; face in quartz and porphyry giving low assays. The south drift, 750 level, is in 116 feet; face in low-grade ore.

ALPHA.—The south drift from the west crosscut, 100 feet north of shaft, 500 level, is out 9 feet; face in quartz yielding low assays.

EXCHEQUER.—The east crosscut on the north line, 600 level, is out 234 feet, face in porphyry.

CHOLLAR.—The south drift, 1400 level, was advanced 9 feet; total from north line, 146 feet; face in hard porphyry. The joint winze in the east crosscut, 1400 level, is down 50 feet; the bottom is in quartz and porphyry. Sent to the mill the past week 529 tons of ore worth \$23.09 a ton as per battery assays.

POTOSI.—The winze is down 144 feet below the 1400 level; the bottom shows porphyry and streaks of quartz. The south lateral drift from the Chollar incline, 1100 level, is out 251 feet; face in porphyry.

UNION SHAFT.—West drift from the shaft, 900 level, is out 369 feet, face in soft porphyry.

NEW YORK.—Northwest drift, 650 level, is out 240 feet; face in quartz and porphyry. North lateral drift, 1100 level, is out north of shaft 533 feet; face in quartz yielding low assays.

SILVER HILL.—The southwest drift, 50 level, is out from shaft 100 feet; face in porphyry. South crosscut, 160 level, is out from winze 575 feet; face in hard porphyry.

ANDES.—On the 420 level east crosscut from main south drift, after being extended a total length of 273 feet, was stopped. East crosscut No. 2 from north drift has been extended a total length of 170 feet. From the crosscut at a point 125 feet from main north drift, a drift has been started north and has been advanced during the week 12 feet in quartz which yields low assays. East crosscut No. 3 from main north drift has been started and is now in 16 feet; face in quartz, clay and porphyry.

Cherry Creek District.

NOT SATISFACTORY.—White Pine *News*, June 13: The new mill at the Star mine in Cherry Creek has been shut down, the new concentrators not working satisfactorily. A gentleman who thoroughly understands the process has been sent for to Colorado, and when he arrives work will again be resumed.

Oseola District.

QUARTZ AND GRAVEL.—White Pine *News*, June 13: A gentleman in from Spring valley informs us that mining matters at Oseola are progressing very favorably. The Cumberland Group has now passed into the hands of the Boston syndicate, and it is expected they will put quite a force to work within the present month. They will sink a shaft and run a tunnel and do other development work on the Cumberland. This mine already has a shaft down 100 feet and a tunnel 80 feet, and has openings at other points, where considerable pay ore has been found, that has averaged \$30 per ton in free gold. The Oseola mine, another of the group, has a vein three feet wide that goes \$25 in gold. It has a shaft down 80 feet and drifts have been run both ways, and some stopping done. The vein has been stripped on the surface for a distance of 600 feet. The Royal Flush, belonging to the same group, has a shaft down 160 feet, with 18 inches of ore in the bottom that mills \$30. The Revenue, still another of the series, has a vein two feet wide on which a shaft has gone down 20 feet. The ore in this mine is said to be better than in any of the others, ranging from \$30 to \$45 per ton. The four claims are owned by the Boston syndicate, and with a reasonable outlay promise to develop into a very valuable property. We are further informed that all the purchase money has been paid up. Boone Tilford is getting rich on his dry-wash claim. He has six or eight men at work, and it is said they average \$10 a day to the man. Boone is in luck and he deserves it for he stayed with the camp in its darkest days. The Gravel Co. has an abundance of water and is tearing down a large amount of gravel, and will no doubt make big clean-up this season.

Pioche District.

WEST HAM MINE.—*Pioche Record*, June 11: The four months bond taken on the West Ham mine by Sam T. Godbe last February for \$5,000 ex-

pired on Wednesday the 9th inst, but the sale was not effected. The prospecting work done on the claim since the bond was given shows up a ledge of good low grade ore, which cannot be profitably worked, however, without the aid of cheap transportation, and the uncertainty attending the construction of the U. P. road to this section is one of the main reasons given by Mr. Godhe for not taking the property. The property possesses merit, however, and will come to the front with a reasonable amount of work performed on it.

Safford District.

COMET.—Eureka Sentinel, June 13: A shipment of two tons of ore from the Comet mine in Safford district, this county, netted \$300.

Tuscarora District.

NEVADA QUEEN.—Times-Review, June 11: South drift from east crosscut on the fourth level of Commonwealth, has been extended 12 feet in the vein.

NAVAJO.—The stopes above the 350-foot level continue to yield about the same, the seam is small but very high grade. Sent to the mill 55 tons ore, assay value \$197.93.

DEL MONTE.—Second level: Have started a drift north from joint raise, also joint intermediate drifts east and west, all of which show a little ore.

COMMONWEALTH.—First level: West drift from shaft in 40 feet, face all in the vein, 18 inches being \$40 ore. Hoisted during week 35 cars ore, assay value \$43 per ton. Fourth level: North drift from east crosscut on fourth level extended 18 feet, still showing bunches of good ore. Crosscut from north drift in 20 feet, ore 20 inches wide, assays \$16 per ton.

NORTH COMMONWEALTH.—Fourth level: North drift advanced six feet, most of the week have been timbering. Hoisted 11 cars first-class ore and 55 cars second class.

BELLE ISLE.—North drift, 350-foot level, extended 14 feet, vein getting larger and the grade of ore continues high. South drift extended 13 feet, still yielding good ore. Have now opened 68 feet in length on this ore, all of which distance shows a good-sized vein of rich ruby ore. The stopes started over this drift are being pushed as fast as possible, and show about a foot of solid rich ore. Have just started to milling, a battery sample shows \$305.39, this is from ore culled from the ore shipped in March. Concentrated 132½ tons, assay value \$26.01, giving 18,200 pounds wet concentrates, estimated assay value \$273.36.

NORTH BELLE ISLE.—East crosscut from the Belle Isle 450-foot level extended 16 feet. No. 2 crosscut, 400-foot level, extended nine feet. South drift from No. 1 crosscut extended 21 feet and connected with No. 2 crosscut. North drift, same place, 18 feet. The stopes above these drifts continue about the same. Six cars of first class and 74 cars of second class ore have been broken. The stopes from No. 4 chute, 600-foot level, continue to show some very rich ore. West crosscut from the 600 station extended 21 feet, rock very hard but breaks well. East crosscut, same place, extended 14 feet; the ground is short and extremely hard. Sent to the Union mill 78 tons, assay value \$255.19. Concentrated 170½ tons, estimated value \$15.45, yielding 19.43 tons wet concentrates, estimated value \$190.70.

ARIZONA.

STARTED UP.—Journal-Miner, June 10: The Copper Basin plant, owned by the Commercial Mining Co., was started up to-day. The plant is a very extensive one. The company has 125 men in their employ at present. General W. O. O'Neil recently received an order from New York for two carloads of onyx from his Big Bug mines. The fact is just becoming generally known that Arizona can produce the finest quality of onyx in the world. A piece of onyx weighing about 60 tons was cut out of the Big Bug onyx claims recently. It is 20 feet long by six feet wide and five feet thick. This is without doubt the largest piece of onyx ever taken out of any mine in the world. There seems to be scarcely any limit to the size of the blocks that the Big Bug mines are capable of yielding. Our correspondent at Prescott Junction writes that the article which recently appeared in the Journal-Miner relative to the new discovery of mineral in National canyon, a tributary to the Grand canyon, has resulted in the receipt of numerous letters of inquiry in regard to it. The original discoverers will shortly make another trip into the canyon, for the purpose of doing some work on their claims. Other prospecting parties have also gone to the scene of the new mineral field. Geo. W. Sines and John Ross, on their return trip from the Bradshaw mountains, recently, picked up a piece of float in Maple gulch which will go away up into the thousands in silver. It is water worn until perfectly smooth, and is what prospectors call "the traveler," as it has the appearance of having traveled hundreds and probably thousands of miles. How it came to the place where it was found, is of course a mystery, as it was found near the summit of the Hassayampa divide, at an altitude of about 7000 feet, where there has never been any ore resembling it in any respect whatever discovered within miles of the place.

COLORADO.

THE LITTLE ANNIE.—Aspen Times, June 11: To-day seven teams are hauling ore from the Annie. The force will be increased to 10 teams to-morrow. Only three teams were hauling last week. All the ore carrying 25 ounces and above is shipped together. The grade of last week's shipments was 39 ounces. If the low-grade ore can be successfully treated there are 5000 tons of 15 to 25-ounce ore on the waste dump. The mine is now in condition to work 20 men on pay ore and 50 more men can be employed on the low-grade mineral. Development work will be kept ahead of stoping.

THE MIDNIGHT.—The Midnight shaft is now down about 200 feet at a point near the east side line and a few feet from the west line of the Iron mine. Some good-looking rock showing lead and native silver has been reached. This is doubtless mineral from the vein west of the porphyry.

MINING SALE.—Denver Republican, June 11: Three good purchases of Red Mountain mines have just been completed through the agency of Denver parties. A total sum of \$332,000 has gone into the San Juan in consequence. Attorney E. W. Waybright returned yesterday morning from Ouray, where he had been to close the purchase of the Car-

bonate King mine for Mr. James McKay of Pittsburgh, Penn. The price paid for the property was \$75,000, cash. The Carbonate King is located on Red Mountain, in the San Juan. The owners of the property had every confidence in it. They had developed it and taken out about \$40,000 worth of ore while doing so, but recently encountered a good ore body and a strong flow of water at the same time. Rather than go to the great expense of machinery they concluded to sell. Mr. McKay is always in the market for a good thing and he did not hesitate in taking it at the price quoted. He will at once put in about \$20,000 worth of pumping machinery and enter at once into the further working of the mine. The deeds have passed, titles been examined and money paid. The former owners were James E. Wood, L. R. Lindsey, J. J. Crooke and others. The Silver ledge syndicate of London, through its American representative, Judge C. M. Campbell of this city, has secured a group of rich Red Mountain properties. The negotiations for these have been pending for over a year, but they are now all but completed. Judge Campbell returned from the camp yesterday morning. The properties in the group are the Silver Ledge, the Addie S., the Iron-Silver, the Morning Star, the Blue Bird, the Turquoise, and the Lone Star. The purchase of the first three is decided upon definitely, and bonds have been taken upon the others until the titles can be fully examined. The price paid is \$50,000 cash and \$135,000 in the stock of the company.

DAKOTA.

IRON HILL.—Deadwood Pioneer, June 11: A gentleman, thoroughly reliable, who was permitted to inspect all the levels of the Iron Hill mine recently, said yesterday that there was an abundance of good ore in the mine.

STONE PLACERS.—Under the recent ruling of the secretary of the interior, the commissioner general of the land office is holding for cancellation all applications for patent as stone placers that are valuable only for stone for building purposes. This ruling was based on the belief that such entries do not properly come under the head of stone placers. This action will unsettle title to a number of various kinds of stone claims in the vicinity of Deadwood that have become valuable as real estate.

NIGGER HILL TUN.—A special dispatch from Chicago announces that C. L. Brondson, who is erecting tin plate works at Aurora, Ill., states that his company has recently purchased an interest in some tin mines in Nigger Hill, and will work them.

IDAHO.

OPAL MINE.—Moscow Mirror, June 10: The Opal mine, discovered last fall near Moscow, notwithstanding the superstition that opals are unlucky gems, is proving a good find for the owners. As high as 150 carats, valued at over \$1000 have been taken out in one day, and the yield of the mine to date has been upward of \$10,000.

POORMAN.—Idaho Avalanche, June 13: The lower tunnel on this mine is now within a few feet of connecting with the shaft. When this connection is made it will furnish perfect ventilation and enable a large force of miners to work to advantage. Plans and estimates are all finished for a new mill at some convenient point near the mine. When the same have been approved by the owners, it is said work will be commenced. The present arrangement is for a mill of 30 tons daily capacity, with power for 50 or more tons.

MONTANA.

PLACERS.—Phillipsburg Mail, June 13: Placer mining is taking renewed activity in the Flint Creek valley this season. Several of the old diggings are being explored again, and some very good results have already been derived. A number of the old flumes are under way of repairing, and some new ones are being considered by the thrifty placer miners in the valley. Several streams of water from the hydraulics are playing upon the gravel banks, and with the abundance of water assured for this season there will be great activity in the placer mining industry this year.

GRANITE MOUNTAIN OUTPUT.—The output of the Granite Mountain Co. for the past week is 46 bars, containing 69,000 ounces silver and 165.6 gold.

WASHINGTON.

DISCOVERIES.—Snohomish Eye, June 13: Several new discoveries have been made in the vicinity of the Vandalia during the past two weeks, probably the most important of which was that by F. H. Coy and Chas. LeFever, two young tenderfeet, who went out prospecting for the first time last week. On the east side of the creek they found a 12-foot vein carrying a fine grade of galena with carbonates. As has been the case in many of the best districts of the country, this lode had been tramped over and overlooked by many old-timers and experts for several years. The boys, highly elated, came down with samples for assay. They will return this week. Jack Wesley is also said to have struck it rich in the same vicinity. Geo. Milliken, mining expert, in the employ of the N. P. railroad company, and Mr. Rust of the Tacoma smelter passed through town last Wednesday on their way to inspect the Silver Creek district. In conversation with a reporter Mr. Rust said: We propose enlarging the plant this season to meet the increasing business and hope to buy Silver Creek and other ores as soon as they can be transported by rail. The R. R. Co. has at the present time in the Silver Creek district several surveyors and mineral experts. Their purpose is to examine the mineral prospects of the district thoroughly and report also on the practicability of building a line of road into the district.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

MINES and Stock in Mines for sale. See advertisement on page 386.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING JUNE 9, 1891.

- 456,767.—TOOLS FOR CUTTING HOLES AND WASHERS—Jas. Addison, S. F.
453,963.—PENDULUM BAR TREADLE—E. A. Cochran, Pasadena, Cal.
453,768.—SAFETY GUARD FOR CARS—L. J. De Puy, Phoenix, A. T.
453,859.—FRUIT-SLICER.—Flickinger & Graham, San Jose, Cal.
453,902.—PLUMS AND LEVEL—Garner and Connaughton, Latourell Falls, Or.
453,769.—ORE FURNACE—J. L. Giroux, Jerome, A. T.
453,636.—BAG HOLDER—E. Henretty, Portland, Or.
453,841.—SAFETY CHECK-REIN HOOK—A. Kempley, S. F.
453,658.—DEVICE FOR STEAMING FRUIT—Phelan & Eldridge, Portland Or.
453,915.—DOOR CHECK—David Rankin, Pasadena, Cal.
453,778.—ADDING MACHINES—A. E. Shattuck, S. F.
453,765.—SHUTTER FOR FIRE GRATES—W. H. Vance, S. F.

The following brief list, by telegraph, for June 9 will appear more complete upon receipt of mail advices:

California—William H. Anderson, Riverside, tag and parcel tyer; Matthew Arnold, San Francisco, riveting machine; Nathan Brown, Oakland, safety guard for sleeping cars; Charles C. Davis, Los Angeles, portable burglar alarm; Geo. W. Hunter, Fresno, axle-setting machine; John F. Kirby, San Francisco, governor; Harry H. Love, Sacramento, two patents, wrench and ruling pen; David Lubin, Sacramento, writing-pen attachment; James and William Paterson, Stockton, assignors to the Benicia Agricultural Works, Benicia, harvester; Edward A. Rice, San Francisco, rock drill; Edgar P. Sanford, Merced, thresher; John C. H. Stut, San Francisco, cable railway gripp; Frank E. Tremper and J. W. Elsworth, assignors to Electric Vapor Engine Company, San Francisco, electric pole in gas or vapor explosive engines.

Oregon—Jacob A. Fulton, Astoria, filter.
Washington—William McLesnon, Port Angeles, pump.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ADDING MACHINE.—Arthur F. Shattuck, S. F. No. 453,778. Dated June 9, 1891. This adding is one of that class in which the spring-actuated plate or plates are controlled by means of a pawl, and ratchet operated by keys. The invention consists essentially of oppositely moving plates, one moving varying distances and the other a given distance, as a result of which, combinations may be made of the first four digits with the fifth to obtain all the digits. The general object of the invention is to materially simplify the construction and operation of this class of adding machines, whereby greater rapidity and accuracy are obtained.

TOOL FOR CUTTING HOLES AND WASHERS.—James Addison, S. F. No. 453,767. Dated June 9, 1891. The invention relates to the general class of machine-tools designed for the cutting of holes in metal plates, boiler-heads, tube-holes, ship-plates and general purposes, and/or the making of washers. The object is to provide a simple and effective tool for these purposes, capable of necessity of first providing a hole for the tool center to act as a guide, and of taking all the strain and spring of the plate upon said center, thereby removing it from the cutters. In ordinary tools for cutting holes or cutting out washers, it is customary to first make a hole completely through the plate. This hole is necessary to receive the center, which serves as a guide for the cutters, and as said center feeds downwardly through the plate it must have a clear passage to move within the cutters. This necessity of making the hole first is entirely avoided by the use of this new machine. Moreover, with this machine, the strain and spring of the plate are taken entirely upon the center, thereby relieving the cutters, which have no more than their legitimate functions to perform—namely of cutting through the plate. Much more rapid and effective work can therefore be performed by this machine, which is at the same time simple in construction and readily operated.

SAFETY GUARD FOR CARS.—Louis J. De Puy, Phoenix, Arizona; assignor of one-half to R. A. Gray, Colusa, Cal. No. 453,768. Dated June 9, 1891. This invention relates to that class of safety-guards for cars in which fenders entirely surround the lower part of the car, and inclosing the wheel space, are employed. The invention consists of the endless movable fender. This fender is normally in a state of rest having no movement relatively to the car at all; but when it comes in contact with an obstructing body, said body being stationary or moving at a less speed than that of the car, it will readily be seen that the fender will be caused to have a movement lengthwise independent of the car by reason of its contact with the body and the movement of the car. If, therefore, for example, a body falls up against the side of the fender, it will thereby be moved on its pulleys while the car proceeds, and the body will soon find itself at the end of the car, where it will be free. Thus there will be no injury to the body, as it will not be pulled or rolled along.

SHUTTER FOR FIRE-GRATES.—Wm. H. Vance, S. F. No. 453,765. Dated June 9, 1891. This is a device which the inventor calls a shutter or door for fire-grates, and which is especially adapted to be open so as to expose the fire in the grate or to be closed so as to entirely shut it off from the room. The sliding doors or shutters, which move in grooves in front of the grate, are made double, so as to leave an air space between the two parts so

they will not be injured by the heat. By the use of these doors the rate of combustion of fuel in the grate may be regulated, and at the same time the heat of the room may be increased or decreased, as desired, by opening or closing the doors. These doors make it possible to leave the room when there is a fire in the grate, without there being any danger of fire falling out and causing an accident.

Mining Share Market.

Comstock mining shares the past week hung around under light trading and fewer cross orders by the pool. The falling off in cross orders was probably done to confirm the prevailing belief that lower prices will obtain before the fall deal sets in. It is generally claimed that the heaviest setback in prices will come in the Middle and North End stocks, for Exchequer, Alpha, Belcher, Challenge, Crown Point and Seg. Belcher, in the Gold Hill group, are too low now to justify any decided break. Those who know what there is in the mines stand ready to buy on a break, or when prices on a gradual setback shade off more. For over nine months about everything has worked in favor of the pool; and they have not been slow to take advantage of the favoring circumstances to force the market down as low as possible to gain stock. After the very low prices in late December, the upheaval in Con. Virginia in May of this year to \$20.50, and sending it down again showed a master-general's hand, for by the break Confidence was destroyed, and large numbers of outside holders of stock sold out. And now comes a report, apparently well authenticated, that papers are drawn up by a mining company, whose patented grounds are to the west of Con. Virginia, to enjoin the latter mine from taking out the very rich ore recently developed to the west on two or more of its levels. Con. Virginia has considerable rich ore of its own that it can take out, without touching the above, yet the pool will undoubtedly handle the injunction for all it is worth, to get more stock at low prices. The pool now has over 150,000 shares, but will not object to having 200,000 shares of the stock. The writer still has faith in a good-sized deal, but top prices may not be reached before next September or October.

In outside shares trading continues slow. The public is seemingly taking very little interest in them. Some day operators will find their mistake and see that it is in them that the largest percentage of gain was to have been made.

An Oakland operator bought Con. Virginia around \$5 a share, and when it got up to about \$19 and \$20 did not sell. He thought the market would not be a sell until Senator Fair's real estate or some other of his large successful speculations were written up by the daily press.

The news from the Comstock mines warrants the belief that the mine managers are pushing work to develop the ore to the west in Sierra Nevada Union and Ophir, and perhaps that in Mexican. In Con. Virginia they are uncovering the very rich ore to the west on the 1100 foot level—a downward continuation of that found on the 800 foot level. They are also developing the 1750 foot level, where there is rich ore. In Hale and Norcross they have run into very rich ore on the 1100 foot level, and are pushing the work to develop the rich ore known to exist about the 1500 foot level. In Chollar, Savage, and Gould and Curry, they are, apparently, making slow progress in developing work—perhaps there is too much stock out yet. There are rumors afloat of a rich find in Potosi, and that in Bullion something good can be looked for soon. Whether the reports are founded on fact or for assessment purposes, we do not know. In Alpha they are preparing to run on a lower level for the rich ore found over a year ago. Quiet but interesting work is being done in Exchequer, Challenge, and Confidence. Miners are looking hopefully to the time when Con. Imperial will start work on or about the 1100 foot level. In Crown Point work is under way to develop the 500 foot level to the west. The superintendent, in his annual report, spoke favorably of this level. The water in Belcher and Seg. Belcher is being lowered, which ought to admit of very important work being commenced soon. In Overman they can take out large quantities of rich ore whenever the pool will allow the supposed manager or managers of the mine to do so. In the Alta group quiet but important work is being done. Never within the history of the Comstock mines was the situation in the mines as favorable as it now is for exciting profitable times.

To-day's advices received from Virginia report that the strike in Hale and Norcross is to the west on the 1100-foot level, near the Chollar line. The ore is rich and ledge large. The strike in Potosi is in the Potosi Bullion south drift.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Geo. Wilson—Sacramento Co.
J. C. Hoag—San Francisco.
F. W. Knapp—Amador Co.
G. B. Gill—San Luis Obispo Co.
E. L. Richards—Escondido, Cal.
Frank S. Chapin—Tulare Co.
B. F. Belt—Shasta Co.
J. H. F. Williams—Tulare Co.
A. S. Cooley—Tehama Co.
Samuel E. Watson—Sonoma Co.
Herbert Stanley—Modoc Co.
C. J. Wade—San Bernardino Co.
J. H. Croosman—San Bernardino Co.
E. H. Schaeffer—Central California.
Wm. M. Hillman—Oregon.
F. B. Logan—Arizona.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

MECHANICAL PROGRESS

Brass and Copper Welding.

To temper copper has always been as great a problem to the metal worker as the transmutation of metals was to alchemists. Second only to this, and really of greater economic importance, is the question of welding copper, brass and a number of other metals. Heated to a certain point, brass becomes extremely brittle, and besides oxidizes so rapidly on exposure to the air as to render welding by the application of external heat, a practical impossibility. But an invention of Mr. J. H. Bevington, and owned by the New Process Welding Co., of Chicago, does away with all difficulties, and that in the simplest manner imaginable. The heat necessary to soften the metal to the welding point is evolved from the metal itself, through the application of friction.

Many say the Chicago *Journal of Commerce* will wonder that the this principle should not long ago have been applied to the welding, drawing and shaping of metals like brass. It must be remembered, however, that the essence of invention lies in a wide, almost universal observation, and an ability to see and take advantage of suggestions, which power, the common mechanic does not ordinarily possess to any marked extent. Mr. Bevington no doubt possesses the power of utilizing suggestions and of combining into something new and valuable, principles already well understood. The inventor, the company and the metal worker, are alike to be congratulated upon this wonderful achievement.

A REMARKABLE RUN OF IRON.—The Mancosla (Mich.) *Herald* says: Stack No. 2, blast No. 1, of the Antrim Iron Furnace, completed the third year of its present blast April 15. Number of days in blast, 1,050, and the total product during that time amounted to 66,347 tons of pig iron—a daily average of 63½ tons. A trifle over a year and a half of this run, or, to be exact, 582 days of it, the stack was blown with a small Weimer engine, with a product of 32 326 tons—a daily average of 55½ tons. The balance of the run (468 days) was made with a large engine of the same make, during which time the product amounted to 34,021 tons—a daily average of 72½ tons. To make this amount of iron, 115,410 tons of ore was used, and 146,000 cords of wood consumed. Had the stack been blown during the entire period with the large engine, the total product would, of course, have been much greater, but the record is a remarkable one, nevertheless, and it is believed that no charcoal stack in the United States has ever made so long a run or so large an amount of iron with a single lining.

LARGE STEAM PIPES COMPOSED OF SMALL ONES.—The immense steam pipes which are necessary for the large-sized engines in use at the Ferranti stations, are composed of numerous smaller pipes bunched together to give the required carrying capacities. This arrangement of the pipes was thought necessary on account of the numerous accidents which have lately occurred from the bursting of large steam pipes in various parts of the world. Just how this arrangement will be accepted by engineers remains to be seen. While there are several good points about this kind of steam pipe, there appear to be also several poor ones. The increased cost necessary for its construction, and the larger amount of surface exposed for condensation, would appear to be somewhat against its being commonly employed. Of the increased safety assured by its use, *The Stationary Engineer* thinks, there can be no doubt, but whether or not it can be called a commercial success, is not so plainly evident. Those who have had experience with it appear to think it answers every requirement.

MISGUIDED ENTHUSIASM OF INVENTORS.—The patent office records testify, remarks a contemporary, to the misguided enthusiasm of inventors in no more conspicuous manner than in hand rock drill patents. There have been, perhaps, as many patents taken out on hand rock drills as on power drills. In every case the inventor aims at something beyond reason. He seeks to do more work with a machine in the hands of a human being than that person is capable of performing. He seems to labor under the impression that a machine creates power, when, as a matter of fact, it only utilizes or transmits power. Every person has a certain capacity for work. He cannot exceed that capacity. He is limited by power, which is represented by strength, and by time, which is represented by endurance. In other words, he is like a lever which may lift a heavy weight slowly or a light weight rapidly, but in each case the weight and the time, when multiplied together, give a result which is the same.—*Ex.*

WIRE 1 500TH OF AN INCH IN DIAMETER.—In an interview recently published, a wire manufacturer made the following statement: "We are at work just now on some pretty small wire. It is 1 500th of an inch in diameter—finer than the hair on your head, a great deal. Ordinary fine wire is drawn through steel plates, but that wouldn't do for this work, because if the hole were away ever so little it would make the wire larger, and that would spoil the job. Instead, it is drawn through what is practically a hole in a diamond, to which there is of course no wear. These dia-

mond plates are made by a woman in New York, who has a monopoly of the art in this country. The wire is then run through machinery, which winds it spirally with a layer of silk thread that is .0015 of an inch in thickness—even finer than the wire, you see. This wire is used in making the receiving instruments of ocean cables, the galvanometers used in testing cables and measuring insulation of covered wires.

AN IMPROVED KNITTING MACHINE.—A new machine is being put on the market by a Dresden, Germany, knitting machine manufacturer, which, in some respects, resembles an ordinary knitting machine, and can be employed as such on round and flat work, but is especially adapted for variegated patterns. It works variegated pattern, cardigan stitch, pearl cardigan, two and two rib, also embodies the peculiarities of a stripping machine, producing in one piece of goods single, colored, striped, and many colored patterns without changing the machine itself. It is also claimed to be capable of producing complete gloves. By the placing in or out of the hack thread in the slotted thread conductor, it is claimed any desired number of shades can be produced, which gives the impression that these patterns had been the result of embroidery.

IMPROVED CAR WHEELS.—A new and practical method for fastening steel tires to car wheels for railway service has been recently announced, which will be looked at by consumers of such with a good deal of interest, for it is the first system ever introduced that gives entire satisfaction. The system lays in placing a small notched steel plate between the tire and wheel, and sending each alternating projection into corresponding grooves in the tire, and the remaining projections are bent over the edge of the wheel, making a solidly fastened tire, and one which will be capable of standing much more wear than has ever been the case.—*Manufacturers' Gazette.*

A NEW DEMAND FOR METALLIC WORK.—A gentleman well acquainted in Australia recently stated that "the people of that continent are in need of metal furniture." He has been in England to secure school desks and seats of light metal which will be durable and cheap, but neither in England nor in America has he been able to get what he wants. He says "the pest of Queensland is the white ant, against the ravages of which sheet-iron roofing and tin-covered chairs are the only protection thus far devised. The ants eat wood of every description, boring the doors and house rafters until they are honey-combed, tables, bedsteads and bureaus suffering similarly."

AN ALUMINUM BOAT.—A late mechanical wonder of the age is a pleasure boat, to accommodate four persons, and which will be made entirely of aluminum, and is to be propelled by electricity, by means of a storage battery also made of this metal. It will be the product of a Pittsburgh (Pa.) plant. Since aluminum, as per latest authentic report, has been reduced to 50 cents per pound, we may soon expect to see this metal more generally applied to fancy boats, yachts, etc.

A NEW GATLING GUN.—Dr. Gatling is working on a new gun, which will knock the spots out of his famous pepper-box gun. His object is to make war so dangerous that nations will have hard work to decide between it and peace.

The London Engineering for May 1st describes a new method of making weldless steel chains from a bar of cross-shaped section, which is drilled through diagonally and the links shaped under presses by punching and shearing.

SHIP RIVETS.—So rapid is the production of ship rivets by machinery that one train of rolls feeds four machines, which turn out 16 tons of rivets in 24 hours, the work going on night and day.

ALASKAN MINING EXPEDITION.—The steamer South Coast left a few days ago for Alaska, with 57 miners for the Amalik and Pioneer gold mines. The principal owners are J. C. Green, who has been managing the mines for the last nine years, and Captain A. M. Brown, U. S. N. Working on a small scale, good results have been obtained, and now an attempt is to be made on a large scale. With this object in view, the company is taking up 55 miners, mechanics and laborers, a stern-wheel steamer of 50 tons, a diamond drill for prospecting, 15 horses, three 50-ton barges, 25,000 feet of lumber, and provisions for 18 months. It is also the intention of the company to build two ocean steamers. The latter will trade between San Francisco and Alaska, and the stern-wheeler will connect with the mines, which are 40 miles inland.

CALIFORNIA MACKEREL.—It is said that samples of mackerel, caught off the coast of San Pedro have been sent East and pronounced superior to the best Eastern mackerel. The writer has seen the ocean between Catalina and the mainland white-capped as far as the eye could see with schools of these fish. Quite a large pack of these fish was made at Catalina last year, and brought the highest price in the Los Angeles market. The fishing industry is bound to be an important one on the southern coast of this State.

SCIENTIFIC PROGRESS.

Counting the Dust in the Air.

One of the most remarkable contrivances of modern times has enabled scientists to count the dust particles in the air, many of which are readily seen by means of a sunbeam allowed to enter a darkened room through a small orifice. To Mr. John Aitken, an ingenious Scotch physicist, the world owes this new and interesting method of research. A report of these experiments has been published in *Knowledge*, from which we condense as follows:

One of the most remarkable contrivances of modern times enables us to count the minute inorganic dust particles in the air. To Mr. John Aitken, an ingenious Scotch physicist, we owe this new method of research.

The bright motes that dance in the sunbeam seem beyond the power of computation, yet by a marvel of mechanical ingenuity Mr. Aitken has counted them, the invisible particles being brought within the range of vision, and even within the limit of easy enumeration.

The method of numbering the inorganic particles depends upon a principle which was established by Mr. Aitken in his determination of the formation of fogs. He showed that without dust there could be no fog, no mist, no rain. Without dust there would be only dew on the grass and road. This principle can be easily illustrated. Let common air be forced through a filter of cotton into a glass receiver, from which the air has been exhausted, and let a glass receiver filled with common air be placed beside it. If steam be now admitted into the receivers, the one containing the common dusty air will soon be dense with fog, while the other containing the pure filtered air will remain perfectly clear. The particles of dust, then, are the free surfaces, which, in certain conditions, attract the water vapor of the atmosphere to form fog. Invisible before, they are touched by the magic wand of a lowering temperature and start into visible existence. The dust particles are clothed all over with the moisture and become fog particles. The above experiment is very simple and may be readily understood.

It then occurred to Mr. Aitken that if a small measured quantity of the common dust-impregnated air be mixed in a receiver with a large measured quantity of dustless air, which has been filtered through cotton, the particles of dust would be some distance from each other, and when these particles were made centers of condensation of vapor by lowering the pressure, fog particles would be formed, which could be counted by means of a magnifying glass. If, moreover, these particles fell from a certain height on a small, measured area, the number could be accurately ascertained. That is the secret!

This more definite experiment was accomplished by a very ingenious device carefully manipulated, by which process Mr. Aitken counted seven and a half millions of dust particles in a cubic inch of the ordinary air of Glasgow. In the air outside the Royal Society rooms four millions in the cubic inch were counted. Inside, at four feet from the floor, but near the ceiling, after the gas had been burning for some time, no less than 49 millions were counted in the cubic inch. After the two hours' meeting of the Fellows, the numbers increased to six and a half millions. He counted in a cubic inch of air immediately above a Bunsen flame no less than 489 millions of dust particles. Of course, when the air is very dense with dust particles, a fraction of an cubic centimeter of the air is introduced into the flask for the experiment, and, when the air contains fewer particles, more than one cubic centimeter is introduced.

The air of Colmonell, in Ayrshire, has been found to contain from 8000 to 155,000 particles in the cubic inch. At Hyeres, in the south of France, he found from 50,000 to 400,000, according to the direction of the wind. At Lucerne, in Switzerland, the specimens of air tested were remarkably free from dust, some even as low as 3500 in the cubic inch—the lowest observation yet made.

The question next arises as to whether 3500 particles in the cubic inch of air is the lowest limit which the atmosphere ever attains to. Even away from the contaminations of smoky towns and villages the air contains cosmic dust. There is always dust in the upper atmosphere, for without the dust no clouds could be formed, and of cosmic dust there must always be a considerable quantity in the air produced by the waste from the millions of meteors that daily fall into it.

"The gay motes that people the sunbeams" are not, therefore, as Milton considered, "numberless." They have been enumerated with marvellous accuracy.

The Odor of the Soil After a Shower.

Some 25 years ago, Dr. T. L. Phipson, F. C. S., devoted much time and study to the above-named subject, but never published the result of his inquiries. Quite recently he learned by a paragraph in the *Chemical News* that Prof. Berthelot and M. Andre are now studying the same phenomenon, but have not yet arrived at

any definite results. Under these circumstances, Dr. Phipson hastens to give to the world his notes upon the subject, which, he says are dated 1865. They possess considerable interest and are given as follows:

After a considerable number of observations, I arrived at the conclusion that the odor emitted by soils and sedimentary strata after a heavy shower of rain in summer was due to the presence of organic substances closely related to the essential oils of plants, and it appeared evident to me that during the hot, dry weather, these porous surfaces absorb the fragrance emitted by thousands of flowers, and give it up again when the rain penetrates into these pores and displaces the various volatile substances imprisoned therein, which are only very slightly soluble in water. I believe that many kinds of soil possess this property, but those on which my observations were first made were the chalk soils of Picardy, in France. I found that not only chalk, but also marls, compact limestones, phosphatic rocks, and some kinds of schists and amphibolites are porous enough to possess it to such a degree as to emit a decided odor when they are strongly breathed upon.

Finding the property of which I speak very remarkable in certain chalk rocks of Picardy, I endeavored to ascertain the nature of the substance or substances to which it was owed. I dissolved a very large quantity of the chalk in dilute hydrochloric acid, and passed the carbonic acid through various media, water, alcohol, weak potash solution, and dilute acid; but none of these liquids appeared to arrest the passage of the odoriferous substance. The only liquid which I found would retain it was an aqueous solution of bromine. This arrested it, and when the bromine solution was afterward carefully evaporated at a low temperature, a yellowish product, soluble in alcohol, and having a strong odor of cedar wood, was obtained, which, from its chemical and physical properties, appeared to be very similar to, if not identical with, bromo-cedren, derived from essence of cedar.

Preserving Milk.

Many devices have been tried to so preserve milk as to retain as near as possible its natural condition. The latest effort is described by the *Scientific American* as follows: Fresh and sound milk not later than one hour after milking is placed in jars made of a suitable material.

The jars are made in three parts. The bottom part, in which eventually the milk is preserved, is first filled; the other two parts together form what is called the mediator. This is screwed into the bottom can and acts as a filler. For this purpose, even after the bottom can is filled, the top filler is kept three parts full.

When a number of cans and mediators have been fixed in a tray, they are filled, and the whole lowered into water in a suitable boiler. The milk is heated up to about 200° F. As soon as the mediator and can are full, by the milk expanding, a tap at the top of the mediator is turned, and the whole is thus hermetically closed. The water in the boiler is then raised "to an intense heat, and this will keep the milk for another 50 minutes at a somewhat high temperature." The jars are next deposited upside down in a cooler, and left in this position for 60–80 minutes. This insures the mixing of the milk, as it is in the nature of the milk that its fatty particles, and therefore the butterfat, will rise to the surface. The cans are finally placed in an upright position. The vacuum above the milk in the mediator is caused by the contraction of the milk. The air-tight stopper between the can and mediator is now turned, and as the ordinary temperature is rather higher, the can will be full, and there is little chance of the fat coagulating, should the cans be shaken. The mediator is opened, and the milk in it having been run off, it is taken off and the process is complete. The milk is said not to lose its freshness, purity and sweetness, even after 18 months or two years in hot countries, and when opened tastes like new milk, fresh and sweet.

SOME RARE METALS, possessing special qualities, are required for certain work. Thus, palladium is used in making some parts of timepieces, and iridium for the points of gold pens. Lithium is the lightest of all metals. Rhodium is extremely hard and brittle, and is only fusible at a very high temperature, and iridium is the heaviest substance hitherto discovered. The unutilized have no idea of the value of these scarce products, which are most of them, far more precious than gold and silver.

THE MOON AND THE BAROMETER.—By a comparison of records extending over a number of years, it has been ascertained that the moon has an influence in lowering the height of the barometer in the months from September to January, at the time of full moon, and in raising it during the first quarter. No effect has been perceived in the other months.

DECREASE OF MOUNTAIN HEIGHT.—No less than four different mountain peaks in Idaho are now from 13 to 23 feet lower than they were 15 years ago. This settling is supposed to be going on in many others. The cause of the settling is generally supposed to be the presence of quicksands at their base.

ELECTRICITY.

Electricity and Industry.

In the census taken ten years ago, a department was devoted to the subject of power used in manufactures, but its reports and tables dealt only with steam and water power, and made no mention of electricity. During the ten years that have intervened, the application of electricity to industrial purposes has been wonderfully rapid. About two years ago, *Electric Power*, a New York journal, printed a list of 150 industries to which the electric motor had actually been applied in this country, and one of the editors expresses the opinion that if a list were now prepared with equal completeness, it would show that the electric motor has found employment in connection with nearly 300 branches of productive industry. The electric motor has been successfully used to run the sewing machines of girls employed in glove making in their own homes, and with the reported result of enabling each worker to accomplish more and better work in less time, and under conditions more favorable to health and causing less fatigue.

With these facts before us, the introduction of electricity as a power applicable to a great variety of industries, and available in the private house and at the individual work bench, is no longer a dream or a prophecy, but an actual realization, of which the possible future development and industrial influences cannot be foretold. One of the principal articles of belief of the cheerful economic creed so ably propagated by Mr. Edward Atkinson, is that natural forces are constantly tending to a distribution of population more favorable to individual welfare. That where men have been too much isolated on great farms and sparsely settled tracts of land, the tendency toward higher cultivation of smaller areas, is operating to bring them into closer and better relations with the world, and that, on the other hand, where population has become too closely concentrated, in crowded cities and towns and over-crowded tenements, the development of rapid transit is operating to secure a distribution over a larger area, and to correct the evils incidental to a congestion of population at industrial centres.

In the latter direction, nothing could be more efficacious than the gradual adoption, in many industries and at many manufacturing centres, of a form of power peculiarly suited to such distribution, as would do away with the necessity for crowding hundreds of operatives together in the work-rooms of great factories. Such a change could be made to bring with it an amelioration of many of the conditions which now occasion most complaint, and to secure for a great mass of workers, more wholesome and cheerful surroundings, less crowded and better lighted and ventilated. Such a change seems like a dream of a return to the days of the hand-loom and spinning-wheel, and its possibility is an answer to much of the sentimental lamentation constantly heard about the changes which time and development have wrought in the condition of the toiling masses. Progress in the application of electricity to the employments of men, is but one of innumerable evidences that an improvement in social and industrial conditions is to be sought in the higher development of mechanical invention, and in the advancement of science, rather than in vain regrets for the simpler life of the irrevocable past.—N. Y. Commercial Bulletin.

ELECTRIC LOCOMOTIVES, which have long been anticipated, but in regard to which expectation has not been warranted by realization, may soon be found in extensive service. The commissioners who have been for some time engaged in devising plans for increased facilities for rapid transit in New York city have decided in favor of the construction of a four track railway, running underground below Canal street and elevated farther up town, to be operated by Bergman's electric locomotives of 300 horse power. This is a new motor in which the power is applied directly to the axles of every car, and it is claimed that the force is capable of propelling a train of 20 cars at the rate of 40 miles an hour, and that a train moving at the highest speed can be brought to a standstill within 12 feet. So much has been claimed for electric motors and so much disappointment has resulted from previous tests that actual demonstration will be required before these claims will be generally accepted; but that electricity can and will be successfully applied to the running of trains not only upon city railways but surface roads now operated, by steam, we continue to have little doubt. It does not take extraordinary faith to believe the predictions of Edison and others that ere long coal burning and smoke and fire producing engines on railways will be superseded by smokeless and steamless locomotives, whose power is furnished by that still mysterious and wonderful agent electricity.—*Railway Age*.

WELDABLE BY ELECTRICITY.—Electric welding has proven quite universal. Experiments have shown that by this means it is possible to make perfect welds with 13 different pure metals, 22 distinct alloys and 27 different combinations of metals as copper to brass, tin to zinc, etc.

ELECTRICAL LITIGATION.—While electricity is constantly increasing in usefulness to mankind in all walks of life the litigation over pat-

ents for electrical appliances has proven a bonanza to the lawyers. It is estimated that all the suits growing out of contested electric patents in this country and Europe have gobled up about 30 per cent of the profits. Edison and his associates have paid about \$3,000,000 for professional services and the cost of litigation.

GOOD HEALTH.

BANANAS AS FOOD AND MEDICINE.—Dr. John Dougall of St. Mungo's College, Glasgow, has a letter in a recent issue of the *Glasgow Herald* on the banana. He quotes from Stanley's "In Darkest Africa," showing that "for infants, persons of delicate digestion, dyspeptics and those suffering from temporary derangements of the stomach, the flour, properly prepared, would be of universal demand." During Stanley's two attacks of gastritis, a slight gruel of this flour, mixed with milk, was the only material that could be digested. It is odd, also, as pointed out in Stanley's book, that in most banana lands—Cuba, Brazil, West Indies—the valuable properties of the banana as an easily digested and nourishing food have been much overlooked. Dr. Dougall has made some experiments in making banana flour. He concludes that it should be made from the ripe fruit at its place of production. In trying to make it from bananas purchased in Glasgow, he obtained on drying the pulp a tough sweet mass like toasted figs, an appearance probably due to the conversion of starch into sugar. Bananas contain only about 50 per cent of pulp, and of this about 75 per cent is water. They would yield, therefore, only one-eighth part of flour.

HUNGER AND INFECTION.—It is a well-known fact that hunger predisposes to certain diseases, but it has been reserved to two Turin doctors to demonstrate the increased liability experimentally. Their observations were carried out with the virus of bacillus anthrax on pigeons, a disease to which these birds are, under ordinary circumstances, refractory. They found, however, that six days' total deprivation of food rendered the birds amenable to the virus, on condition that food was still withheld. If, however, food was given at the same time as the virus, then they still successfully resisted infection. Further, when starvation was continued for two days after the inoculation, and food then given, the development of the disease, though not prevented, ran a slower course. Lastly, the virus proved capable of infecting birds well fed up to the date of inoculation, but starved subsequently. The line of investigation is evidently one which admits of further research, but the moral is obvious.

SANITARY SCIENCE.—Sanitary science, says the *Sanitary News*, is a science that does not relate to the earth we live on, or to the heavens we live under, but to the conditions of the homes we live in. We can live on the earth or under the heavens, without knowing much about them, but to live best in our homes, we must know them well. Geology cannot change the conditions of the earth beneath us, or astronomy those of the heavens above us, but sanitary science can change from unhealthy to healthy the conditions of the homes we live in. Is it not, then, a science worthy of study? It touches the highest interests of mankind, cleanses and purifies the present generation, and will strengthen and will glorify posterity. The effects of obedience to its laws are not remote, but immediate. They touch the everyday life of all, and enter into all the relations of life. They give strength and vigor to whatever capacity in which human endeavor is put forth.

TO PREVENT "SOUR STOMACH".—Some physicians prescribe the following as a preventive of "sour stomach": Avoid eating foods which ferment easily, such as sugar, potatoes, and the like. Drink hot water to wash the stomach out, say one cup about one hour before eating. This prepares the organ for the kindly reception of the food. Avoid fluids at meals, unless it be peptonized milk, which really is a semi-fluid food. It might be well to use the peptonized milk for a few days and eat nothing else. Should this not agree with you, eat scraped beef, broiled, using with it but little salt, and dried whole wheat bread. Be careful to not eat too much meat in hot weather, as it is quite heating. You may try for a drink a half-cup of cold skimmed milk, filling the cup with boiling water. Should you not be relieved by following the above, you had better hunt a sanitarium.

THE DOCTOR WHO SUCCEEDS.—A physician who understands human nature, who plays with the baby, makes friends with the children, and listens to the woes of the good wife and mother, says a medical journal, is the fellow to whom the master of the house most cheerfully pays the largest bills. It isn't the medicine that's bottled up, but it's the comfort and consolation that are unbottled that mark the broad line between an unsuccessful and a popular physician.

We lose about two pounds of water in 24 hours by perspiration, and the more we perspire the cooler we become. There are 27,000,000 pores on the surface of our bodies, which, if placed in line, would extend 28 miles in length.

ENGINEERING NOTES.

Pacific Coast Bridge Building.

Bridge building on the Pacific Coast has become quite an important feature in our engineering works. The great steel bridge across the Columbia river, at Vancouver, will be a mammoth concern. It will be 6000 feet from the Washington to the Oregon shore, and it will be double-tracked, with roadway on top for teams, and will be erected upon pneumatic piers. The pivotal pier, or draw pier, will support a draw which will give an opening of 200 feet space on either side for vessels to pass, and the span immediately south of the draw span will be 375 feet. Whole structure to be of steel, built ten feet above the high water of 1876, and 40 feet above low water. On account of the sandy formation, it will be necessary to go down 80 feet below low water to get a firm foundation. This gigantic structure will cost over \$4,000,000. It will be January 1, 1892, before the cars can pass over it. The company is pushing the bridge, and also the road, as fast as men and money and their present perfected plans will permit.

Another improvement in this direction is a new steel drawbridge of 315 feet span across the tidal canal, Oakland harbor, which, when completed, will form a very substantial structure.

There are several bridge-construction companies in San Francisco which are fully able to perform the best class of work in that line. The San Francisco Bridge Co., in addition to bridge building, are also largely engaged in railway building and canal construction.

The California Bridge Co. has done some very superior work in the construction of the Downey avenue and First street bridges in Los Angeles. Among other bridges contracted for by them is the steel draw-bridge on the San Francisco & North Pacific R. R. at Petaluma of 227 feet span. A Baltimore truss bridge built by the company near Salinas, Monterey county, is of two spans of 300 feet each, and is doubtless about the maximum size that has been built in combination work. The combination cantilever over the North Umpqua river, in Oregon, has a river span of 290 feet, with shore arms of 147 feet, and, aside from being a novelty in bridge construction, is the only structure of this type on the coast, excepting the Fraser River cantilever.

The King Bridge Co. of Cleveland, Ohio, has a branch concern in San Francisco in charge of Col. G. A. Eberhardt, which has done more or less work in almost every county in this State.

The Pacific Bridge Co. is the only one which builds suspension bridges extensively. They have built some of 400 feet span for carrying timber flumes across the mountain valleys. A number of bridges in the Sandwich Islands, some work now under way in China, and the recent completion of an iron pier at Ocos, Central America, shows the extent of the company's business territory.

As has been correctly stated by a contemporary, the majority of the Pacific Coast engineers have come here from the far East, adapting, as far as possible, Eastern ideas to Western material. Having an abundance of good timber and of unlimited length on this coast, fewer panels have been used and longer joists. The engineer back East who clings to 12 or 13 foot panels, either from choice or from inability to obtain long lumber, would be surprised to find that here panels of 25 feet are not at all uncommon.

MODERN PROGRESS IN PALESTINE AND SYRIA.—The work of laying the railway from Jaffa to Jerusalem has been actively resumed. The section between Jaffa and Ramleh is on the point of being finished, its length being about 25 miles, or about half of the whole distance; the other half will take about a year to complete. By the middle of next year, therefore, pilgrims will be able to go by rail from Jaffa to the Holy City, instead of hiring vehicles for which exorbitant prices are charged. On another part of the Syrian coast great improvements are in progress. The new harbor works at Beyrout, which had to be stopped on account of the heavy weather of the past winter, are again in full activity, and are expected to be finished in two years. The new port will form a basin nearly 900 yards long, by means of a jetty of this length almost parallel with the coast, and connected with the latter by a mole of 160 yards at one end, and one of 328 yards at the other end, with an entrance protected from the westerly currents. Like the railway from Jaffa to Jerusalem, the harbor works at Beyrout are being carried out by a French company.

THE LAST SCHEME for railway communication between England and France provides for a double tube, capable of containing two railway tracks, sunk about 40 feet in the channel. It is proposed to utilize the displacement and buoyancy of the tube to give the necessary support, piles being driven into the channel, to which the tube would be chained to prevent it rising.

ENGINEERS MUST STUDY.—A few years ago, says the *Stationary Engineer*, no one dreamed that in so short a time the electric light would become a regular part of the equipment of mills and factories. It was only when the dynamo found its place in the engine-room and

the incandescent light sparkled in the shops and workrooms that the engineer found anything of special interest to him in the study of electricity. Now he must study it whether he will or no, and though the knowledge he most requires must be of a practical nature, he must have a goodly amount of theoretical or "book" information in order to understand what he is doing.

USEFUL INFORMATION.

Cause of Forest and Other Fires.

The increasing frequency and wide devastation caused by forest fires is causing much uneasiness in the Eastern States. To assign the cause of such fires as a general thing is impossible. But there is a practical unanimity about the excessive carelessness. Many forest fires are supposed to be started intentionally in sparsely settled districts by whortleberry pickers, as it is well known that land where that berry flourishes furnishes a largely increased amount of such fruit for several years after being burned over.

Farmers often debate the following question: "Is it better to refuse a tramp lodging, and incur his hatred, or let him sleep in a barn, and burn it by smoking?" Mining accidents have often been caused by carelessness, but wise supervision has resulted in a marked decrease in explosions. The way matches are scattered about in private homes and business offices is appalling. Without knowing, it is reasonable to suppose that many forest fires are due to the carelessness of smokers, or to the thoughtlessness of men who fail to see that their campfires are thoroughly extinguished. There will always be incendiaries, but they form only a small fraction of society. It is not deliberate crime so much as carelessness that is responsible for these outbreaks.

The annual statements of sums paid out by fire-insurance companies seem large, but the actual marvel is that the number of fires is not much larger than it really is. Recklessness seems to be the rule, and prudence the exception. Boys scatter explosives for weeks before and several days after the Fourth of July. In nearly every factory, the careless manner in which kerosene is handled causes dread apprehensions among the timid. Constantly, half-consumed but still-burning cigars are thrown away. Thrown on a pavement, they are probably extinguished by the heel of the next pedestrian, but if thrown on the dry leaves of the forest, they may do terrible damage.

WOOD PULP MAKING, by the sulphite process is thus briefly described: The wood is peeled, discolored or decayed parts are removed, the wood is cut across the grain into thin chips, which are elevated to the top of the mill and dropped into large drums, about 14 feet in diameter, 24 feet long, and strong enough to sustain a pressure of from 75 to 200 pounds to the square inch. When packed full of chips, the drum is filled with sulphuric acid and other chemicals, and the cotton-like product is pressed dry and mashed, mixed with water, rolled flat and cut into shape for bundling, being 60 per cent moisture and 40 per cent fiber. Thus it goes to the paper-mill. One cord of spruce makes 1200 pounds of dry fiber, worth from \$1 to \$1.50 a hundred pounds. Freight is paid on the water contained rather than use dry pulp, which packs hard. A sulphite plant that will consume from 8 to 15 cords of wood every 24 hours, will cost about \$10,000.

A PERFECTLY BLACK PAINT for bass tubs is made as follows: Take two grains of lampblack, put into any smooth, shallow dish, such as a saucer or small butter plate, add a little gold size, and thoroughly mix the two together. Just enough gold size should be used to hold the lampblack together. About three drops of such size as may be had by dipping the point of a lead pencil about half an inch into the gold size will be found right for the above quantity of lampblack; it should be added a drop at a time, however. After the lampblack and size are thoroughly mixed and worked, add 24 drops of turpentine, and again mix and work. It is then ready for use. Apply it thin with a camel's hair brush, and when it is thoroughly dry the articles will have as fine a dead black as they did when they came from the optician's hands.

THE USE OF LUMINOUS PAINT appears to be rapidly on the increase, especially in some European countries. The new luminous paint, of German manufacture, by which oil or water colors, shining at night with white, red or blue tints, as may be desired, can be sold at retail at about \$1 a pound. At this price, the cost of covering a square yard of surface would be about 17 cents, so that it is likely to come into general use for painting the interior of cellars and other dark places. The luminous paint known as the Balmalm paint, which is manufactured in England, has been held at \$9 a pound, at which price it is too expensive for general use.

A NEW BOOT-CLEANING MACHINE cleans boots at the rate of a pair a minute, and is worked in the same manner as a sewing machine.

The period of a generation is said by a scientist to have increased from 30 to 42 years.

TABLE OF CONTENTS.

EDITORIALS.—Columbian Exposition Buildings, 385. Paeslog Events; We Shall Be Obligated; Plumas Gravel Miners; The Mining Display at Chicago; River Mining; Tail-Ropes; Miscellaneous, 392. Preventing Dust Loss in Furnaces; Laneell's Balance; California Pig Tin; Miscellaneous, 393.

ILLUSTRATIONS.—The U. S. Government Building; Buildings of the State of Illinois; Machinery Hall at the World's Columbian Exposition; Principal Facade of Agricultural Building, World's Columbian Exposition.—From the Original Drawing, 385. Arrangement of Tail-Rope and Pulley; Balance for elevator Cages, 393.

MECHANICAL PROGRESS.—Brass and Copper Welding; A Remarkable Run of Iron; Large Steam Pipes Composed of Small Ones; Misguided Enthusiasm of Inventors; Wire 1-50th of an Inch in Diameter; An Improved Knitting Machine; Improved Car Wheel; A New Demand for Metallic Work; An Aluminium Boat; A New Gatling Gun; Miscellaneous, 390.

SCIENTIFIC PROGRESS.—Counting the Dust in the Air; The Odor of the Soil After a Shower; Preserving Milk; Some Rare Metals; The Moon and the Barometer; Decrease of Mountain Height, 390.

ELECTRICITY.—Electricity and Industry; Electric Locomotives; Weldable by Electricity; Engineers Must Study, 391.

USEFUL INFORMATION.—Cause of Forest and Other Fires; Wood Pulp Making; A Perfectly Black Paint; The Use of Luminous Paint; Miscellaneous, 391.

MINING SUMMARY.—From the Various Counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 388-389.

MINING STOCK MARKET.—Values in the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, etc., 396.

MARKET REPORTS.—Eastern and Local Metal Markets; Coal and Coke, etc., 396.

MISCELLANEOUS.—A Lixivation Plant; Hydraulic Mining; Gold in Nevada, 387. A Four Months' Prospect; The Ansonia Co.; Electrical Chlorination; Free Coinage of Silver; Spelling a Mining Deal; The State Fair; A High Explosive; Free Coinage, 387.

Passing Events.

An event of local as well as national importance is the receipt of the first commercial shipment of pig tin from the mines in San Bernardino county, this State. Steady shipments are promised and arrangements are being made to increase the monthly output above what is now possible with the appliances at hand.

The decision of the U. S. Circuit Court in Montana, on the railroad and mineral land cases is a severe blow to the mining industry of that State. The Montana Miners' Association, which has actively contested the cases and assisted the individual defendants, will carry the case to the U. S. Supreme Court now that the Circuit Court decision in an important suit has favored the railroad company.

The Plumas county miners have associated themselves together to contest the injunctions brought against the small hydraulic mines of that region. It is contended that these mines do no harm to the men and might be permitted to run without damage to farming lands.

PROGRESSIVE MINING.—The Central Nevada says: S. L. Cohoon went to Austin, Tuesday, to bargain with T. B. Hutchinson, superintendent of the mines, relative to boring holes by means of his artesian-well machinery, from the surface to a number of underground crosscuts now lacking a supply of air for working purposes.

We Shall Be Obligated.

The publishers of the PRESS would consider it a favor for subscribers to renew their subscriptions during the coming month. Many of those whose subscriptions have expired, or are about to, would probably not inconvenience themselves but would oblige us by promptness in sending in the money. A settlement of this kind from several hundred readers is of material assistance on occasion though the amount may be small from each. The price of the PRESS is sufficiently small so it should be little trouble for our subscribers to answer this appeal.

The Railroad Defeats the Miners.

It will be remembered that in Montana there has been a long-continued contest growing out of the mineral land cases along the line of the Northern Pacific railway, where the railroad claimed the mineral land in their grant. The miners who had taken up and were working claims on their lands have been fighting for their rights, and there has been organized action among them as against the railroad. Now, Judge Sawyer of the U. S. Circuit Court, has rendered a decision at Helena, which, if it stands, will give the railroad company title to some of the best mineral land in Montana.

The case was that of the Northern Pacific R. R. vs. R. P. Barden et al. In 1888 Barden took up a mineral claim about three miles from Helena, on a section of land granted the railway by Act of Congress. By this Act mineral lands were withheld from the railway. The road filed its map of proposed route through Montana in 1882. Miners of the State have all along contended that the exclusion of mineral lands included that known to be mineral at the time the building of the road was in progress.

Barden's case was hacked by the Mineral Land Association of the State, and was submitted to Judge Sawyer, whose opinion is exhaustive, and is, in effect, that to exclude any lands granted the Northern Pacific railway, they must have been known to be mineral lands prior to the location of the line in 1882. Judge Knowles of the United States District Court dissents from this opinion, and the case will be carried to the Supreme Court.

Plumas Gravel Miners.

The miners of Plumas county recently held a meeting at Quincy to discuss the methods of dissolving the injunctions now existing against the operation of the hydraulic mines of the county. J. W. Thompson of American Valley, Richard Thompson of Spanish Ranch, and A. W. Whitney of Crescent, were appointed a committee, with full power to act for the miners, to collect funds, employ counsel and adopt such other measures as they may deem necessary to accomplish the result aimed at.

Concocted action of this character is exactly what is needed by the miners of any one section. The opposition is thoroughly organized, but the mining community is not. If, as the Plumas miners claim, their mines are doing no injury to the rivers, they should see that the facts are properly presented to the people of the Sacramento valley. There is quite a difference between the big hydraulic mines and the small ones of Plumas, which are 100 to 200 miles from Marysville. If the debris people cannot be made to see the justice of the claims of the Plumas miners, then they can fight the question out in the courts and abide by the decision.

THE MECHANICS' INSTITUTE.—The agent of the Mechanics' Institute reports that 20 firms, representing all classes of machinery except laundry and woodwork, have applied for space in the coming exhibition. He is trying to induce the State Board of Trade to place their exhibit in the pavilion during the fair and has sent circulars all over the State calling upon producers to send samples of their products to the exhibit. Mr. Graves, the agent, also recommended that medals be awarded for meritorious inventions, and stated that 82 applications for 37,725 square feet of space were on file.

The United States and Great Britain have come to an agreement to prohibit the killing of seals in the Behring sea until next May. Meantime a number of sealing vessels have left this port to engage in work in the Arctic, and revenue cutters have been sent up to enforce the law.

The Mining Display at Chicago.

California Collections Already Made.

The Board of Control of the National World's Fair Commission has confirmed the appointment of F. J. V. Skiff, of Colorado, as Chief of the Mines and Mining Department of the World's Fair at Chicago. This appointment was foreshadowed some weeks ago, but it is now settled that Colorado gets this office.

We are not informed as to the intention of the California Commission with regard to a mining display from this State or if they have given the matter any consideration as yet, most of the interest so far having been centered on the subject of horticulture. But if this State is to be properly represented in the mining department it is time for the preliminary steps to be taken. It must be confessed that as far as individual miners are concerned, they are rather apathetic on the subject, and it will take several energetic men several months to arrange for a suitable display.

There is one way, however, that California could excel them all, and with very little trouble or expense, and that is to send the present collections belonging to the State, bodily, and not attempt to make a special collection. The collection of minerals, metals, etc., in the State Mining Bureau Museum is the finest in the country. The State University has the collection of the State Geological Survey, the Voss collection, Hanks collection, Keene collection and several others. These are all classified, arranged, identified and labeled. Each county and district in the State is properly represented. Every department of the mining industry has its separate place with locality indicated. No other States or Territories of the Union have any such collections as belong to California now. There are no other mining bureaus to make such collections, nor have any of them spent the money we have.

Special collections were made here for the Paris, Philadelphia, and New Orleans Expositions, and many of those specimens are in the Mining Bureau. The gathering of these samples has been going on systematically for years. Meantime, they have been grouped and classified with care and scientific accuracy. Unless there are legal obstacles to taking the collections out of the State, there can be no reasonable objections. The university could keep its working collections used by the Professors of Mineralogy and Geology, but all the rest could be temporarily spared. The Mining Bureau Museum we could do without for a few months, for ten thousand people would see it at Chicago for one person here.

In fact it would seem to be but justice to the mining community to ship these entire collections to the World's Fair. Few people here at home, have much idea of the mining resources of the State. The newer mining States, and the more prosperous ones such as Montana, Colorado and Utah, will make strong efforts to excel in this line, while we have it in our own hands to excel them all put together.

Of course it would be necessary to send men with their collections to re-arrange them. But it would be a simple matter in view of their present condition, stamped and labeled as they are. All the gold ore, silver ore, huddling stones, quicksilver ore, borax, manganese, coal, iron, copper, etc., are not only grouped in separate cases, but there are county displays as well, showing the varied mineral products of each county. Then there are colored geological maps, photographs of mines, published reports, models, casts, etc., all relating to the mining industry.

The State Mining Bureau is intended to advertise the mining industry, and it can do no better thing in that direction than co-operate in the manner suggested. The whole collection could be in immediate charge of the State Mineralogist himself. That from the University could be under the supervision of some one connected with that institution.

As to making a special collection, that is a thing involving labor, time and expense. Moreover, it is not possible to do this as easily as in former times. The miners will not bother with collecting specimens. This State has a wider variety of mineral products than any in the Union. Several are obtained here only, and we are still the leading gold-producing region.

We have now an advantageous opportunity

which may never occur again. Our collections are large and complete, and beyond all possibility of competition. It will open the eyes of miners from other sections to see what California can show. It is greatly to be hoped that those who have the matter in charge will consider this suggestion, for it is an assured fact, if these collections can be sent, that California can carry off the palm of the mining display at Chicago.

River Mining.

In the early days of mining in this State, river-hed mining was one of the most profitable forms of the industry. Nearly all the rivers of the Sierra, in the gold belt, were worked more or less where the circumstances permitted. Of late years this industry has been confined more to the northern rivers, such as the Klamath, most of the main rivers and tributaries in the central part of the State having been pretty well worked out. Some extensive enterprises, however, have been inaugurated for working large tracts of river-hed, but no startling success has been met with so far. These are tunnel or flume schemes by which the entire water of the river is diverted from the bed for some distance and are different from the ordinary wing-dam plan by which the bed is usually got at. In some seasons, when the water runs unusually low, the river miners reap a rich harvest; on other occasions they are apt to lose all their mining appliances and the fruits of their labor for the summer by a rise in the river.

It is stated by the Grass Valley Union that river mining in the bed of the South Yuba will have a revival this season, as since the stoppage of hydraulic mining the river has scoured out along its course, and below the junction with the Middle Yuba down to the vicinity of Smartsville. This will permit the turning of the stream by wing dams, and to get down to bedrock without the removal of large deposits of gravel that a few years ago were accumulated along the stream from the hydraulic washings. For this reason a number of new locations were made last season, and one company, consisting of residents of Grass Valley and Pleasant Valley, located two miles of the river bed below Bridgeport, doing the necessary work to hold the ground, and this year it is proposed to turn the river and carry on systematic operations. A portion of the ground has never been thoroughly worked, and the locators are confident that they have ground that can be worked to a good profit. The river is yet too high to commence work, but in four weeks more it is intended to start in for the season, as by that time the water will have fallen sufficiently to commence the construction of wing dams. It is the common belief that there is plenty of gold in the bed of the Yuba that can be taken out to a good profit by those who understand river mining.

Tail-Ropes.

Percy's "Engineering in Collieries" says that when an engine is fitted with a cylindrical drum has a clear shaft, and a sufficiently deep shaft, good results are obtained by placing a tall or balance rope under the cages. But with any other drum, and when the shaft is full of pipes, etc., and when the sump is not sufficiently deep, tail-ropes are not advisable.

Mr. C. F. Clark, of the Garwood Coal and Iron Co., Victoria, gives the Mining Commissioners the particulars of the pulley arrangement applied to his works, and shown in the cut on this page. The pulley on the sump, under ordinary circumstances is stationary, but is free to move up or down as may be required but it is very effective in keeping the balance rope right. The tail-rope makes the load uniform, but adds very seriously to a somewhat tender part of the winding rope—namely, the capping with the usual winding arrangement the load upon the capping is the cage and tubs and fuel and this load is constant.

But with the tail rope arrangement we add to the load upon the capping the entire weight of the tail rope, which may amount to as much as the load itself. Mr. Clark made some experiments years ago, with and without the tail rope and found an unquestionable gain with it. The engines started their load with a lower pressure of steam, and a winding could be made with the same pressure of steam in considerably less time. But the particular shaft

was not convenient for the appliance. Water had to be wound very often with a tank swung under the cage, and there were many landings, pipes, etc., on the shaft, which made it scarcely safe to have a tail rope dangling about. The diagram shows the general arrangement of the balance or tail rope and pulley in the snmp. Chains instead of ropes are sometimes adopted and they need no pulley in the snmp, form no loops and work very steadily.

Preventing Dust Loss in Furnaces.

Joseph L. Gironx of Jerome, Arizona, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency an improved ore-roasting furnace the object of which is to pre-

any material falling upon it will automatically slide down toward the front.

At one corner of this dust chamber is an outlet stack which leads upwardly from the chamber in a vertical direction and serves for the discharge of the products of combustion after they have entered the chamber through the supplemental stack. At the bottom and front of the chamber is the fine-dust feed-opening, leading into a spout, the opposite end of which discharges into the furnace again. This feed-spout is about two and a half feet wide by four inches deep where it opens out of the dust chamber and about two inches deep where it delivers into the furnace, so as to prevent any special draft through this passage.

Ore is fed into the furnace in the usual way,

Lansell's Balance.

On May 16th, we gave in the PRESS illustration of Lansell's mining balance which is for the purpose of equalizing strains on winding gears such as are used on mining shafts. The invention consists mainly in coupling the auxiliary winding drum or spider to the shaft of the main winding gear, and on attaching to this auxiliary drum or spider a rope or chain of increasing weight to act as a counterpoise to the cage and hoisting rope. This rope or chain hangs down either the pump shaft or down a blind shaft or bore-hole, adjacent to the winding gears.

This invention can also be applied to an elevator for office buildings or warehouses.

Columbian Exposition Buildings.

(Continued from page 385.)

very near the shore of Lake Michigan, and will be almost surrounded by the lagoons that lead into the park from the lake. The building is to be 500x800 feet, its longest dimensions being north and south. The north line of the building is almost on a line with the south pier leading out into the lake, on which heroic columns, emblematic of the 13 original States, will be raised. The general cornice line is 65 feet above grade. On either side of the main entrance are mammoth Corinthian pillars, 50 feet high and 5 feet in diameter. On each corner and from the center of the building, pavilions are reared, the center one being 144 feet square, and those at the ends 64 feet square.

The main entrance leads through an opening 64 feet wide into a vestibule, from which entrance is had to the rotunda, 100 feet in diameter. This is surmounted by a mammoth glass dome, 130 feet high. All through the main vestibule, statuary has been designed illustrative of the agricultural industry. Similar designs are grouped about all of the grand entrances in the most elaborate manner. The corner pavilions are surmounted by domes 96 feet high, and above these tower groups of statuary.

Inside, broad staircases lead to a gallery 28 feet wide that extends around the building. About 400,000 feet will be available in the building, and by the widening of the gallery, 90,000 square feet of additional space may be secured.

The State of Illinois, being the host, and having made the largest appropriation of any of the States, will have a specially fine building. The structure in the main is 160 feet wide by 450 feet long, with the school-house about 75 by 60 feet, taken out of the east end and within the building. The dome will be 72 feet in diameter and about 200 feet high, with a lookout about 80 feet high and another in the lantern about 175 feet high. The side walls are 47 feet high, while the centre wing on the south will be 72 feet high, and both ends 54 feet, with a still higher projection in the centre.

On the north the Memorial Hall will form a wing 50 by 75 feet, while on the south will be placed the executive offices in a wing 75 by 23 feet, carried up three stories, with a public hall in the third story. In addition to these offices there are to be others in each of the four corners for the departmental officers. The building is to be embellished with fine carving and statuary, the material to be cast blocks of some approved composition. In front of the entrance there will be stone terraces with railings, statues, and stone steps leading down to the roadway.

California Pig Tin.

The first shipment of American pig tin, consisting of 207 bars, weighing about 56 pounds each, is now in this city for sale. With the quantity previously sent for exhibition, there are now about seven tons on hand. This all comes from the Temescal mines belonging to the San Jacinto estate, Limited, San Bernardino county, California.

This announcement is a very important one, since it proves the advent of a new branch of the mining industry in California and in the United States. Both California and Dakota have deposits of tin ore, but this State is the first one to put the metal on the market on a commercial basis. The amount is small, it is true, but the company expects to be able in a year hence to turn out 2500 tons of pig tin per annum. When it is known, however, that the average tin product of the world is only about 9000 tons, the advent of a new producing region is of recognized importance.

The only drawback to the satisfaction which we should all have in seeing this new California product is the knowledge that the mines from which it comes are under English ownership. The mines belonged to Americans in this State for many years, but were never developed, owing to litigation mainly. When legal ownership was finally determined, the mines passed almost immediately into the hands of an English corporation, which is now developing them. American capitalists do not seem to interest themselves in tin mines, and the Dakota people expect their needed assistance from across the ocean.

It remains now for Dakota to follow suit and ship pig tin in commercial form. Little specimen blocks have been shown for some years—in fact, both the California and Dakota mines were scarcely believed in because they had been so long known and showed so little result. California has now proved its position in a practical manner. The Temescal mines have tin for sale and more coming. Now let us hear from Dakota.

ARRANGEMENT OF BALANCE ROPE & PULLEY

ARRANGEMENT OF TAIL-ROPE AND PULLEY.

cipitate and automatically return the lighter dust particles into the furnace and prevent their being carried away and lost by the draft through the stack. The main stack extends up from the body of the furnace in the usual manner, and is provided with an ordinary cover or damper, by which its top may be closed. On starting up and until the furnace is in condition for operation, a free draft passes through this main stack; but when work is commenced, the cover is closed so as to prevent any more draft through the stack.

An inclined supplemental stack extends outward and upward from the side of the main stack, and its mouth opens into a chamber situated at a suitable distance from the furnace, and in such a position that the supplemental stack opens into it at or near the center. This chamber is about ten feet square on the top, having the front upward of 11 feet in height, and the rear wall about four feet, the supplemental stack leading through an opening into the front. The bottom of this chamber is inclined sharply enough by this construction, so that

and, the cover being closed upon the main stack, the products of combustion will pass through the inclined stack into the large dust-chamber where the draft through the supplemental stack will be so deadened and reduced that any dust which may have been carried up through this stack will be deposited upon the inclined floor of the chamber, and this dust will, by gravitation, slide down the floor and through the dust-passage so as to be again delivered into the furnace to be properly roasted. By placing the outlet stack in the chamber out of line with the supplemental stack the continuity of draft through these two is broken, and the dust is delivered into a comparatively quiet atmosphere in the chamber, which allows it to be deposited, and returned automatically as described.

The Bragg Manufacturing Company of California has begun suit for over \$750,000 damages against the cities of New York and Brooklyn for alleged infringement of a horse-releasing device patent obtained by Robert Bragg.

BALANCE FOR ELEVATOR CAGES.

The one given herewith shows the application. The rope of the counterbalance chain is simply wound in the reverse direction on the drum or main shaft of the winding gear in a manner so that its whole weight will act as a counterbalance to the rope and cage.

THE EXTENSION DRIFT MINE.—From a private letter, we learn at the Bald Mountain Extension drift mine, Sierra county, the new dump and reservoir will be completed in a few days, when gravel will be washed in quantities. This will afford the long-waiting stockholders, who have been paying assessments some years, an opportunity to obtain handsome dividends at last. Already a large price is offered for the stock, but the owners prefer to await dividends. A large boarding-house will be put up as soon as the working crew is sufficiently increased to warrant it. The owners of this claim have been patient and persevering, as it has taken a long time to develop it properly, and many thousands of dollars have been expended. From this time on, regular dividends are expected.

A Great Repository of Practical and Scientific Information.

One of the Fullest, Freshest and Most Valuable Handbooks of the Age. Indispensable to Every Practical Man.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing. Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case. Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

PARKE & LAOY CO., General Agents, San Francisco, Cal.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and absolutely water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated. Price, \$2 each, or the entire instrument finished in gold plate, \$5.

N. W. MOODEY, Fresno, Cal.

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safe in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blast ing Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

MARSHUTZ & CANTRELL.

The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers and other ore crushing machines now before the public.

THE BLASDEL CONCENTRATING BELT COMPANY.

We have now made arrangements to have our new Concentrating Belt manufactured in San Francisco; we can therefore fill all orders on short notice. The length and width of these belts are the same as is used on the True or Triumph Concentrating Machines, but can be made of any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth.

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.

121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS, Varying from the fraction of 1 up to 15 and 20-horse power, unequalled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

THE PELTON WATER WHEEL CO., 121-123 Main Street, San Francisco, General Western Agents.

NOTICE TO GOLD MINERS!

SILVER-PLATED AMALGAMATED PLATES

For SAVING GOLD!

IN QUARTZ, GRAVEL, OR PLACER MINES. MADE OF BEST SOFT LAKE SUPERIOR COPPER

AT REDUCED PRICES.

Our plates are guaranteed, and by actual experience are proved, the best in weight of Silver and durability. Old Mining Plates Replated, Bought, or Gold Separated. THOUSANDS OF ORDERS FILLED.

Agent for HOSKINS'

HYDRO-CARBON ASSAY FURNACES

IMPORTANT TO GOLD MINERS!

SILVER-PLATED AMALGAM PLATES for SAVING GOLD

In Quartz, Gravel and Placer Mining.

PRICES GREATLY REDUCED ONLY REFINED SILVER AND BEST COPPER USED. OVER 3000 ORDERS FILLED. FIFTEEN MEDALS AWARDED. Old Mining Plates can be Replated. Old Plates Bought, or Gold Separated. These Plates can also be purchased of JOHN TAYLOR & CO., Corner First and Mission Streets, San Francisco.

SAN FRANCISCO GOLD, SILVER AND NICKEL PLATING WORKS,

E. G. DENNISTON, Proprietor.

653 & 655 MISSION ST., SAN FRANCISCO, CAL.

Our Plates have been used for 20 years. They have proved the best. We adhere strictly to contract in weight of Silver and Copper. SEND FOR CIRCULAR.

RECEIVED EVERY MEDAL Awarded on the Pacific Coast for Silver-Plated Amalgam Plates and Best Gold, Silver and Nickel Plating.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1886.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

Gyrating Screens for Coal.

Anthracite coal as it comes from the mine is not marketable. The "run of the mine" cannot, as in the case of bituminous coal, be sold. It is deemed important to have the lumps of as nearly uniform size as possible and also to make as large a number of different sizes as can be produced without too great expense. It is essential to remove all dust, which depreciates the value of the coal on the market; and the impurities, such as slate, etc., must also be removed. For sizing the coal there are used fixed or movable bars and fixed or movable screens. The movable screens are among the most important parts of a breaker. They are of two types. In the first type the screening surface forms a cylinder and revolves about its axis. In the other type the screening surface is approximately horizontal, and the motion and action very similar to that of an ordinary hand-screen. In many cases the screen is moved back and forth in an approximately horizontal plane. In other cases the horizontal screen receives a gyratory motion, like the motion a molder gives to his sieve when screening his sand. This type of screen is used in the Iron breaker at Drifton Collieries, Pa., and has been described by Eckley B. Cox before the American Institute of Mining Engineers.

Both the single and double gyratory screens are shown in the accompanying cut. The great advantage of this form of screen is, that the whole surface is constantly in action, while in the revolving screen of say five feet in diameter, only about eight inches of the entire circumference is at any one time in action. The problem of constructing a gyrating screen, when it is to be large and must make a great number of sizes, is to support it in such a manner that it will gyrate easily and safely, and at the same time that it will be self-contained, so that the centrifugal force will be counterbalanced and will not shake the building. This has been done successfully.

The method consists essentially in supporting one horizontal plane upon another by means

of three or more double cones, while the motion of gyration is given to the upper plates by a crank upon a shaft passing through and journalled in the lower plates. The cones roll freely in a prescribed path on the lower plate, while the upper plate moves upon the other end of the double cone, its relative motion to that of the cone being the same as that of the bottom plate. The result is that every point on the upper plate describes a circle of the same diameter (in coal screens about four inches), but no two circles have the same centers.

The cones are guided in various ways which the cuts explain. In one form on the upper and lower plate there is an annular V-shaped track, which fits into a corresponding groove in the cone. In another form the guiding is done by an annular groove in the running plate and

a corresponding annular enlargement of the cone at the outer edge. In two other types the guiding is done by a ball and socket joint at the two points of the cones. All these forms work well in practice.

A large number of the single gyrating screens are running at the Cross Creek collieries. The screen box is four feet wide and six feet long giving 24 square feet of screen-surface per shelf. From two to six screens are used. The smaller the size of coal the closer are the shelves put. The boxes are from one to two feet deep. The double gyratory screen did not at first work so well, as it was found that when the number of gyrations per minute exceeded 110 to 120, a very serious shaking set in. It was also found that the best results required from 140 to 145 gyrations per minute. Therefore, a comparatively light counterbalance was put on a shaft connected to the outside of each box, which removed the difficulty and allowed the screens to run smoothly at the required speed. About 20 different sizes of holes have been used with coal to suit different circumstances. There is no clogging of the holes, their circular form and the tendency of the pieces of coal to move in a small circle, cause the holes to clean themselves without difficulty.

Mines on Odd Sections.

One point made by Judge Sawyer in his decision concerning the railroads and mineral land in Montana is a very strong one. He says in effect that the time at which the land must be known to be mineral, in order to exempt it from the railroad grant, must be fixed somewhere, or else a title to a given tract that might be found to contain minerals at any time in the future would be insecure and valueless. The principle conveyed here is doubtless correct. Judge Sawyer holds that the time fixed by the present law is the date at which the map of definite location was filed and accepted. Whether the Supreme Court will sustain him in this view remains to be seen.

The people of Montana are anxious to have a final definite decision from the Supreme Court of the United States settling this matter of ownership of mineral land on odd sections. If it is finally decided in favor of the railroad, the company will own immense tracts of mineral land and the miners must buy from them. This is the case in certain parts of this State where there are drift mines. It is to be hoped that the Montana people will force some suitable case to issue in the highest court.

NUMBER II.

[Read by C. A. STREBELT, San Francisco, before the American Institute of Mining Engineers.]

5. Apparatus for Raising Stock-Solution to the Storage-Tanks.

Plunger-Pumps.—Pumps of the Knowles type, as made and kept in stock by manufacturers, are not durable in contact with byphosphite solutions, none of the metals or their alloys resisting its corroding action. To make such pumps durable, valves, valve-seats and plungers should be made of hard rubber or glass. It is difficult to induce manufacturers to take such orders except at extravagant prices. The same objections apply to centrifugal and rotary pumps.

Pumps of the Koerting Type.—Such pumps must be made of material not affected by the solution. Their principal objection is the dilution of the solution by condensed steam.

The Geyser Pump.—If into a pipe, open at both ends, and immersed in a well, compressed air is introduced at the lower end, the solution in the pipe rises and is discharged, together with the air, at the upper end. The invention of this pump dates back several centuries, and it has recently received from Dr. Werner Siemens the appropriate name, "Geyser Pump." In the *Engineering and Mining Journal* of December 28, 1889, I have fully described it as Pöhle's Air-Lift Pump, and, on the basis of the investigations of Messrs. Behr and Browne, of San Francisco, recommended its introduction in lixiviation-works. After I had made actual working-plans, however, for its introduction, some disagreeable features presented themselves, so that its application for raising stock-solution was abandoned. The objections consisted principally in the necessity of sinking a well, 30 feet deep, for the submergence-pipe, and in supporting a vertical solution-pipe, 85 feet high.

The Montejus System.—A Montejus is an iron tank from which a solution is raised through a pipe by admitting steam or compressed air above the solution. (For protection of the inside, see 13.) With steam, the tank should be in the shape of a long cylinder of relatively small diameter, standing upright, to avoid condensation as much as possible. With compressed air as motive power, the shape of the tank is not material. It is then best to place it so that the axis of the cylinder is horizontal. One of the heads of the cylinder is put on with bolts and a gasket, so that the interior can be easily coated with an asphaltic compound.

These tanks have two openings; one at the bottom, through which the tank is filled and discharged by a three-way cock, connected with the pipes leading to the solution-sump and the storage-tank; one on the top, through which air escapes while the tank is filling, and steam or compressed air is introduced to elevate the solution, which changes are also effected by a three-way cock.

For works of large capacity, two Montejus are placed side by side below the solution-sumps, so that one is filling while the other is discharged. They should hold about 200 cubic feet. Convenient dimensions are: four feet diameter and 16 feet in length, or 4½ feet diameter and 14 feet in length, with solution-pipes from three to four inches diameter.

For large works, compressed air deserves decidedly the preference. The size of air-compressor, which should give about 30 pounds pressure per square inch, is the same for a geyser-pump as for a Montejus of equal capacity.

Although the effect of compressed air is better if applied to a geyser-pump than to a Montejus, the difference plays no important part in economy, while the original outlay for installation is in favor of the latter.

6. Apparatus for Increasing the Rate of Lixiviation.

Suction-Hose.—The means hitherto employed for increasing the rate of lixiviation, have been to give the hose of the solution-outlet below the filter of the ore-tank great length, and discharge the solution at considerable depth below the tank, taking care that the hose remains filled with solution, and creates a suction by the weight of the solution-column. This method is objectionable, not only because it is difficult to get rid of all the air below the filter, but also for the reason that the solution has to be raised again to the precipitating-tanks, unless a very steep mill-site permits their position much below the ore-tanks.

Pumps.—These are not recommended for reasons given in section 5.

Koerting Ejectors.—A Koerting ejector is effective provided it is not made of material liable to be corroded by the solution. The lead-lined ejectors, sold by A. Allen, New York, are not durable; even the platinum steam-nozzle wear out. Ejectors of porcelain, with hard rubber steam-nozzles, are manufactured by the Koerting Brothers, Hanover, Germany. The great objection to a Koerting ejector is, however, the dilution of the solution by condensed steam. The apparatus also acts intermittently, unless carefully regulated to meet the capacity of the filter.

Montejus.—The best effect is unquestionably produced by a Montejus. For this purpose the opening at the bottom is connected with a pipe through which, by a three-way cock, the solution either runs in from the hose at the bottom of the ore-tank, or is raised to the landers in communication with the precipitating-tanks.

The outlet on top has a pipe with a three-way cock, through which compressed air can be introduced for raising the solution, or a suction is created by a Koerting vacuum-pump for filling the tank, or communication is shut off both from the air-compressor and vacuum-pump, provided the apparatus is idle. Only one Koerting vacuum-pump, producing a vacuum of 68 cm. quicksilver, is needed for a number of Montejus tanks, the latter being all in communication with a pipe, at the end of which the Koerting is placed.

These vacuum-pumps are best obtained from the Koerting Brothers, Hanover, Germany.

Necessarily, the operation of the apparatus is intermittent, but the discharge of the Montejus takes such a short time that this is not detrimental.

7. Apparatus for Circulating Extra-Solution.

In circulating extra-solution of standard composition, only a quantity is used sufficient to saturate the charge in the ore-tank, and this is allowed to filter repeatedly and continuously through the ore. As will readily be seen, the Montejus system cannot be used for this purpose. Here we must rely either upon a Koerting ejector, made of porcelain, or use the geyser-pump. Which of the two deserves the preference is doubtful, the geyser pump being untried. Their respective advantages and disadvantages may be stated as follows:

With the Koerting there is risk of decomposing extra-solution with formation of sulphates and CuS₂, the solution coming in contact with the hot steam, and of weakening the solution by dilution. The heating, however, is beneficial. Circulation is also quicker by material increase of the rate of lixiviation.

In the geyser-pump, the extra-solution comes in contact with air only whereby it may deteriorate through the conversion of the sodium hyposulphite into tetrathionate, but without affecting the onerous hyposulphite. By this reaction, and by the evaporation of water, the extra-solution will gain in concentration. On the other hand, the solution will be redosed in temperature, and circulation will be slower, because the rate of lixiviation will not be materially increased, even by taking the submergence-pipe as long as practicable. The original cost of installation, and the expense of running, would hardly enter into calculation. Only an actual comparative test can decide which apparatus is the better.

8. Filter-Press and Press-Tank.

For lixiviation-mills of various capacities I recommend Johnson's filter-press, with 24 to 36 chambers, 15 to 18 inches in diameter, without distance-rings and with closed delivery. Closed delivery obviates the necessity of having a sump below the press, the solution being at once raised to the main solution-sump.

If it is desirable to free the precipitates from adhering stock-solution, for reasons given in my paper on, "Refining of Sulphides," a filter-press should be used in which the cakes can be washed after the chambers have been filled.

The chambers are of cast-iron, with a coating of asphalt varnish, which should be occasionally renewed.

The proper way of charging the filter-press is by a press-tank. In Mr. Daggett's paper, (*Trans.*, XVI., 438.) a press-tank is illustrated and described, constructed for steam-pressure. For works of large capacity, steam should be replaced by compressed air. In the latter case the wooden diaphragm and the pipe extending to the bottom are superfluous, and the precipitates are discharged through an opening in the side of the tank near its top.

The construction, as shown in the cut, is not recommended. The bottom as well as the top should be made of boiler-iron or steel-sheet, not of cast-iron. At the Marsao mill, one of these tanks exploded, by breakage of the cast-iron bottom, at a pressure of 80 pounds. For compressed air the tank should be constructed to be safe for 150 pounds pressure to the square inch.

9. Drying-Chamber for Precipitates.

A drying-chamber for sulphides and other precipitates, is illustrated in the paper just cited, pp. 440 and 443. Its construction is contrary to all rules for a good system of drying by hot air. A chamber of this kind, in use at the Marsao mill, has a very low efficiency. Correct principles of construction are to heat the air by a coil of steam-pipes, in a separate chamber attached to the dryer, to allow the heated air to enter the drying-chamber at the top, and circulate downward between the iron pans charged with precipitates, and finally to withdraw the moist air at the bottom by a Koerting steam-jet ventilator. Upon these principles all modern apparatus for desiccation is constructed.

The outlet of the steam-pipe may be either connected with a steam-trap or with the mud-drum of the boiler. The latter can only be done if the boiler is so located that its mud-drum is lower than the outlet of the coil. In this case the coil works on the gravity principle, the most economical method of utilizing the heat of the steam. The coil should be tested for leakage at a pressure of 80 pounds.

(To be Continued.)

DELICATE HEAT MEASURES.—The degree of delicacy which has been attained in the application of the radio-micrometer for the measurement of radiant heat, viz., from a candle, a fire, the sun, the moon, the stars, or anything

else which radiates heat, through space, is marvellous. An appreciable effect is produced on the radio-micrometer by a candle placed two miles away, at which distance its light is almost comparable to that of a barely visible nebula. The latest measurements by Prof. Bays show that the heat of the lunar rays can be definitely determined as 150,000 times greater than those of a candle 20 feet away. The difference of radiations between a moon 19 days old, which goes through the sky with its dark edge foremost, and the nine-day moon, in which the bright edge goes forward, and the diminished heat at the terminator, as compared with the luminous part of the disc, show in a wonderful way the discriminating power of the instrument. Prof. Bays' experiments fully confirm the inference drawn from earlier observations, that the heat of the moon does not accumulate by penetrating beneath her surface; it lasts only from moment to moment, as supplied by the sun.

The Malay Gold Mines.

Consul Rounseville Wildman, writing from Singapore, contributes to the U. S. Consular, reports the following:

On Sept. 22, 1890, I gave the Department some details in regard to the newly-opened gold field at Raub, province of Pahang, Malay Peninsula, and cited the result of the first crushing of ore. On the 27th of Dec., 1890, the following telegram was received from the superintendent by the local secretary of the Raub-Australian Syndicate (limited), in this city:

KUALA KUBU, Dec., 27, 1890.

Crushing finished. Four hundred and ninety tons stone yielded 760 ounces smelted gold. Left to-day with gold for Singapore via Salangore.

BIBBY.

The above return does not average out as high as the previous one, but it is stated that the fact arises, not from any diminution in the quantity of ore, but rather from the vein running through some former Chinese diggings. The complete output of the Raub mine is at present about \$30,000 in gold.

Mr. Bibby, the superintendent, called on me to obtain data in regard to process of mining by electricity in my own State (Idaho). In conversation he informed me that the development of gold in the Malay Peninsula was but a question of a few months, and that their greatest drawback at present was a scarcity of experienced miners; that, with a corps of American miners to direct the Chinese coolies in the building of timber shoots and in the handling of the ore to the best advantage, the work could be pushed to a rapid financial success.

He further stated that the ground was of a soft shale formation, with plenty of fuel and water at hand.

They are now figuring with American firms for a 100-stamp mill, water-wheel, and electrical machinery, and hope therewith to open a section of country that will compare favorably with the old gold fields of the United States and Australia.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

PNEUMATIC STREET CAR CO., June 2. Object to construct and operate street cars, propelled by pneumatic power. Capital stock, \$500,000. Directors—J. J. Scriver, L. C. Pressley, W. S. Lott, C. A. Henry and C. E. Staples.

SAN ANTONIO M. CO., June 3. Location, Mexico. Capital stock, \$2,000,000. Directors—I. C. Stump, Lloyd Tevis; L. T. Haggin, T. J. Schuyler and F. G. Dunn.

GUANACERO M. CO., June 3. Location, Mexico. Capital stock, \$2,000,000. Directors—I. C. Stump, Lloyd Tevis, L. T. Haggin, T. J. Schuyler and F. G. Dunn.

ASSURED MUTUAL BUILDING AND LOAN ASSOCIATION OF SAN FRANCISCO, June 3. Capital stock, \$2,000,000. Directors—D. L. Randolph, H. M. Black, T. R. Bannerman, D. Sheerin, W. E. Reardon, B. J. Clinch, J. J. O'Farrell, J. J. Tobin and J. F. Sheehan.

LIVE STOCK GAZETTE PUBLISHING CO., June 3. Capital stock, \$50,000. Directors—R. J. Crist, J. A. Crist, A. D. Bell, E. Heymans and J. E. Slinkey.

TULLER G. M. CO., June 3. Capital stock, \$500,000. Directors—D. W. C. Morgan, R. E. Wilson, S. C. Mills, R. M. Anthony and C. F. Liege.

IMPERIAL JEWELRY CO., June 3. Capital stock, \$50,000. Directors—W. Trondorf, G. A. Treadwell, M. J. Morley, and Jno. C. Rice.

PAVILION ROLLER SKATES CO., June 3. Capital stock, \$25,000. Directors—L. Glass, B. W. Bales, J. Wreft, C. W. Nevin and F. T. Carroll.

RAPID SAFETY FILTER CO., June 6. Capital stock, \$150,000. Directors—R. H. Lloyd, C. L. Ackerman, W. D. Mansfield, Chas. Hart and Albert Cerf.

WOMAN'S CLUB FOR PHYSICAL CULTURE. Directors—Abby P. Cheney, Alice Hastings, Joanna M. Wright, Mary P. Murphy, Hattie M. Morton, Minnie C. T. Love, Ida F. Davis, Helen A. Carter and Fannie W. Bancroft. No capital stock.

FRANCO-AMERICAN WHALEBONE CO., June 6. Capital stock, \$1,000,000. Directors—J. B. Bernstein, M. S. Eisner, James M. Seawell, Thos. E. Ryan and Max Blum.

POSO CREEK FRUIT CO., June 6. Capital stock, \$32,000. Directors—T. K. Stetler, Chas. L. Patton, W. R. Smedburg, Wm. E. Lutz and L. P. Bolander.

PACIFIC UNION-ALLIANCE PUBLISHING CO., June 8. Object, to conduct a general publishing company in S. F. and San Jose. Capital stock, \$50,000. Directors—J. W. Hines, Wm. M. Lang-

ton, J. K. Phillips, P. R. Martin and Geo. E. Hines.

JUDSON DYNAMITE AND POWDER CO., June 13. (Oakland.) Capital stock, \$2,000,000. Directors—Egbert Judson, Thos. Bell, J. B. Randol, M. W. Balshare and John S. Doe.

WESTERN FUSE AND EXPLOSIVE CO., June 13. Capital stock, \$50,000. Directors—Egbert Judson, Alonzo Hayward, E. G. Lukens, Gustav Sutro and L. L. Brownell.

LIGHTNING FILTER CO., June 16. Capital stock, \$350,000. Directors—L. T. F. Walter, C. J. Carroll, H. Adams, R. Drew, J. W. Sperry, H. Wells and Frank Dalton.

CALIFORNIA INVESTMENT ASS'N., June 13. Capital stock, \$200,000. Directors—A. M. Cor, J. C. Quinn, C. F. Curry, W. L. Stowell, E. W. Peabody, F. A. Kinne and D. S. Richardson.

CALIFORNIA EXCAVATING AND CONTRACTING CO., June 13. Capital stock, \$1,000,000. Directors—J. H. L. Turk; L. C. Parke, F. Homer, E. E. Tucker and S. W. Elliott.

DROBAZ FISHING CO., June 13. Capital stock, \$100,000. Directors—M. Drobaz, J. Morizio, T. J. Monahan, A. Francovich and A. Mikulich.

Machinery for Handling Gravel.

Working Auriferous Material in Australian Drift Mines.

The Chiltern Gold Mines Co. has, owing to its success and the magnitude of its operations, always occupied an important position, contributing largely to the prosperity of Chiltern district, Victoria, Australia. They first began to use steam machinery in this field as far back as 1860, and several companies sunk shafts. From a length of 2420 yards eight companies took out \$250,289. Moreover, very large quantities of gold were also obtained in the dry workings on the Chiltern lead and tributaries of which there is no record.

The Sons of Freedom claim was registered in July, 1860, in the names of 32 shareholders, who obtained dividends amounting to £16,000. It was subsequently formed into a public company under the name of the Extended Sons of Freedom Co., and very profitably worked under the management of Mr. Henry Nickless. To convey an idea of the judgment and care that must have been exercised to enable him to carry to fruition the responsible duties attached to the position, it may be mentioned that the mine in a few years yielded gold to the value of £161,900. In the year 1870 an amalgamation was effected with adjoining claim-holders, and a new company organized under the style of the Doma Mungli Gold Mining Co. New and more powerful machinery was obtained, but, unfortunately, through an error of judgment it was erected in a wrong position. The continuation of Chiltern lead was not discovered, and although a considerable quantity of gold was obtained, to the value of about £137,328, the ultimate result was most disastrous to the shareholders, and the entire property passed into the hands of the Hon. J. A. Wallace and a Melbourne syndicate. The machinery was removed, and the claim has been most successfully worked of late years under the able management of Mr. John Cook. The quantity of gold obtained from the 4th of August, 1877, till the 15th of October, 1889, was \$2,022,021.64wt. Forty dividends were declared during that period, amounting to £77,905. The claim is held under miners' rights, and is fully 1600 acres in extent. It comprises the outlet of an area of about 72 square miles of auriferous country. Bounded on the north and south by schistose ranges, it occupies the narrowest portion of the valley of the Black Dog Creek; through it all the mineral leads originating in the surrounding country must necessarily trend toward a main channel.

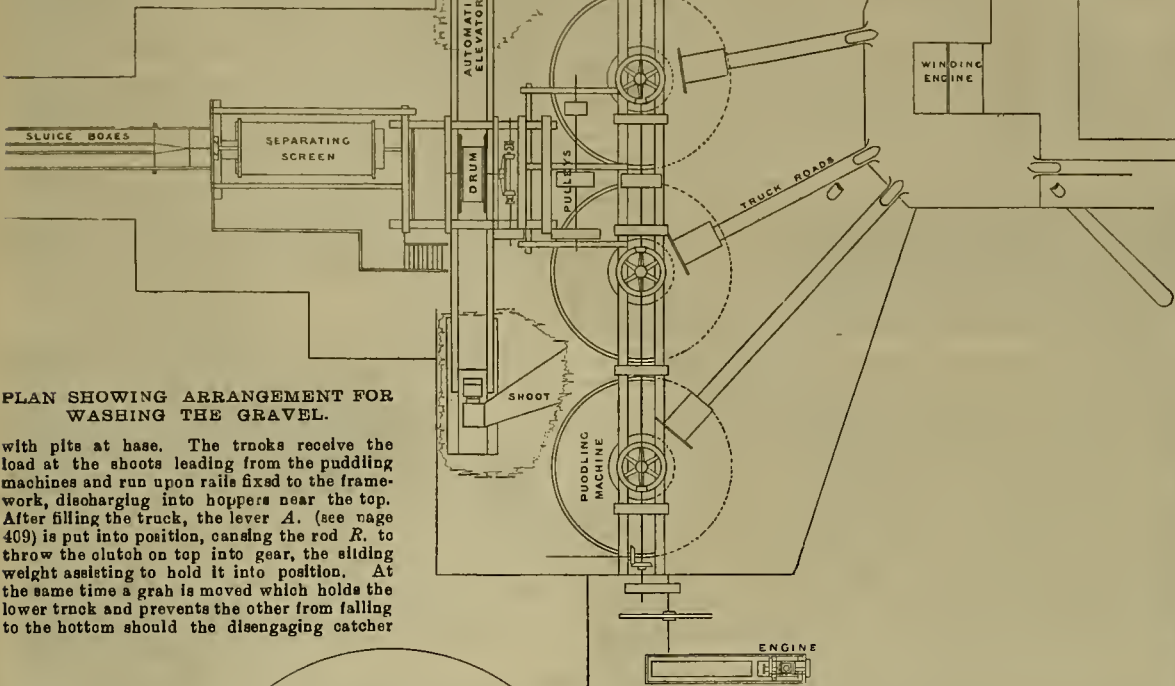

Comparatively little of the 23,100 feet of the total length of the company's claim has yet been worked. The lower portion of the workings present strong indications of drifts peculiar to the valley and principal sources of the Black Dog creek. Previous workings are supposed to have been exclusively confined to the extension of the Chiltern lead, which originates in a purely schistose country, while the rock formation of the valley referred to consists largely of granite and palaeozoic claystone and sandstone; there are also considerable areas of Silurian rock intersected with auriferous quartz veins. It is reasonable to assume considerable gold must have been carried with the detritus from the denudation of this area, and naturally augmented the richness of the lead below the present workings. In the present working shaft of the company, known as No. 2, the bedrock is 280 feet from the surface, and the depth of overlying drift or washdirt is from three to six feet, by a width of from 150 to 400 and occasionally 600 feet. About a mile and a half westward, a series of bores have been put down, where the depth of bedrock appears to be about 320 feet, overlaid by about five feet of washdirt, with good prospects of gold. The company constantly employs about 180 men, independent of wood-cutters. The yield of gold fluctuates greatly, depending on the width of lead, but the output sometimes considerably exceeds 1000 ounces per month. The method of working adopted is by means of main drives constructed in the slate and sandstone rock at a lower level than the auriferous drifts. By this system, large areas can be mined with comparative safety, without injury to the permanent workings, and the heavy expenses of new shafts are not incurred for long periods.

Besides the working shaft, there is the pumping shaft, used for drainage and ventilation purposes, also a balance shaft for sending down

timber, about 1800 feet distant from the working shaft. There have been constructed about 8000 feet of main and branch lower level drives. The machinery consists of a 21-inch cylinder pumping engine, 42-inch stroke. The winding engine is an 18-inch cylinder engine, affording efficient power to haul two trucks in each cage.

The puddling engine is 20-horse power working from puddling machines and all other machinery connected with sluicing operations. The mine manager, Mr. Cook, furnishes for the annual report of the Secretary of Mines of Victoria detailed drawings of this machinery, which are reproduced herewith on pages 403 and 404.

The automatic elevator consists of a triangular framework supporting drums, levers, etc.,

PLAN SHOWING ARRANGEMENT FOR WASHING THE GRAVEL.

with pits at base. The trucks receive the load at the shoots leading from the puddling machines and run upon rails fixed to the framework, discharging into hoppers near the top. After filling the truck, the lever A. (see page 409) is put into position, causing the rod R. to throw the clutch on top into gear, the sliding weight assisting to hold it into position. At the same time a grab is moved which holds the lower truck and prevents the other from falling to the bottom should the disengaging catcher

PLAN THE TRUCK.

GRAVEL TRUCK.

fail to open the truck door. Attention is called in this case by the lower truck being held in a position too high for filling, and to release which it is necessary to first empty the top one. The door of the descending truck is closed by a wrought-iron bow attached to the top hopper. The trucks travel at the rate of 210 feet per minute.

The operation is as follows: The material on leaving the machines falls into a hopper, and is lifted at the will of an operator to a height of about 70 feet by a most ingenious contrivance. It consists of two wagon-like trucks or skips of a capacity of about 8½ cubic feet, fitted with wheels, which run on rails on opposite inclined planes, lined with sheet iron. They are attached to a wire rope wound round a drum actuated by belts from the driving shaft of the puddling machines. The skip to be filled is caught and held firmly by a grab to the outlet of the receiving hopper; the attendant then lifts a small door, and when the skip is filled he actuates a lever and it ascends and discharges its contents automatically into another hopper, the skip on the opposite side having descended to be loaded in a similar manner. The machinery works effectively, and there is little or no danger to be apprehended from accidents. A stream of water is introduced into the upper hopper, which causes the puddled washdirt to flow freely through an aperture, in such quantity as is required, into a rotary cylinder screen 12 feet in length and 5 feet in diameter. It revolves about six times per minute, and has an incline of about 1 foot in 8 feet toward the discharging end. It is constructed with rectangular steel bars, 2 inches by ½ inch in sectional area, which are easily replaced when required. The spaces between the bars are less than 1 inch, through which the detritus containing the gold falls and is carried direct to the sluice-boxes, the larger gravel, which is thoroughly washed, falling through the lower end of the screen into a large truck to be wheeled away when filled. The sluice-boxes are of iron, 54 feet in length, fitted with cast-iron riffles throughout, of a pattern that has been found by experience to answer all practical purposes for saving gold. The upper end of the boxes is fitted with perforated cast-iron plates of special construction; these and a portion of the upper boxes are secured by lock and key, from which the gold is removed daily, and the boxes are washed down every alternate day. It will be seen the entire work of sluicing is practically attended to by one man, which under the ordinary system would have required the labor of four men, thus effecting a considerable saving. The apparatus throughout is admirably arranged, and reflects great credit on the designers, Mr. John Cook, the manager, and Mr. Thos Duncan, the company's engineer. The rotary cylinder screen is simple, not costly, and as arranged it is undoubtedly most effective, and Mr. Cook certainly deserves well of the mining public for

having re-introduced with many improvements such a valuable accessory to sluicing operations. No attempt has been made to obtain a patent for the invention and improvements, which can be utilized by those who may wish to apply them.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—*Cor. Amador Ledger*, June 20: Operations have been resumed at the North Star. The shaft is being repaired down to the 600-foot level, from which point they are going to drift south, a decision which meets with the approval of all concerned. There is 150 feet yet to drift to reach the line of the Comet claim. If nothing is met with in this distance, they may conclude to run into the Comet ground, which they have the privilege of doing by paying \$1000 for each 100 feet of drift. The company have bonded the Comet for \$18,000, to be paid in installments. If nothing is struck in drifting south, they propose to crosscut west. The work the company have mapped out will take in the neighborhood of one year to accomplish. Work at the South Eureka is going ahead satisfactorily. The shaft which is 5x14 feet in the clear, is down 50 feet. The water wheels for the hoist are in place. Fifteen tons of pipe iron will be delivered in a few days from the East, and C. O. Mitchell has secured the contract to make the pipe, which will be 15 inches in diameter. Fifteen hundred feet of it will be required. The contractors, Ed. Kay and V. S. Garharini, of Jackson, have commenced building the hoisting works, and expect to get through with it in two weeks. Work at the Lincoln continues. The mill is kept going, and is about paying expenses. They are crosscutting in hope of striking something of a more encouraging character. At the Hector things are moving lively. The mouth of the old shaft is to be retimbered at once, and then the water will be taken out, and explorations below will be commenced. D. K. Valentine will remain here, and personally superintend the operations.

BUNKER HILL.—Pumping operations at the Bunker Hill have ceased, and the mine is filling up with water. This is a bad indication. It shows there is little prospect of a speedy adjustment of the difficulties, and carries the impression that the property is doomed to a lengthened period of idleness, pending the settlement of its financial difficulties. This is a severe blow to Amador. The Bunker Hill is considered a good mine, and was in a fair way, as far as its underground development is concerned, of entering upon a long career of prosperity when this unfortunate complication with the Eastern stockholders occurred.

Mono.

THE BODIE MINES.—*Miner*, June 17: The mining outlook for Bodie at present is better than for years past. More men are employed, and there is a great deal of activity throughout the entire camp. A feeling of confidence prevails, and all seem to think that this summer will be an unusually lively one. Many old Bodieites who left here years ago have returned, and express themselves as having faith in the future of the place. While Bodie may perhaps never again be as lively as it was ten or eleven years ago, there is every reason to believe that she will continue for many years to be one of the leading bullion-producing camps in the State. Below will be found a brief review of some of the principal mines.

SYNDICATE.—Here we find about 12 men employed, and the mine looking well. The mill was started up on the sixth inst, and will probably run the balance of the month. From the complacent smile on Sam Tyack's countenance it is evident that the cleanup will go a long way toward making a millionaire out of that gentleman.

THE EVA.—This mine adjoins the syndicate on the southwest and is the property of Loose & Trevathen. It was discovered by them a little over a year ago, since which time they have done a large amount of work on it. They have now out a large quantity of ore, which is being crushed at the Miners' mill. The mill has been fitted up at great expense. If pluck and energy and perseverance are deserving of success then Loose & Trevathen will surely succeed.

STANDARO.—Everything is running along smoothly. The different ore bodies in the mine are looking extremely well. The bullion shipment for May was \$21,078, and Superintendent Benedict informs us that this month it will be about the same.

THE BULWER has quite a large prospecting force at work, and if street rumors prove true the Bulwer will soon begin crushing ore again.

BODIE AND MONO.—The character of the work going on is such that an ore body is liable to be uncovered at any moment.

THE SIGOURNEY, situated on Sigourney Flat, a trifle over two miles south of the town of Bodie, is a new silver mine owned by J. B. Skewes, and one that is destined to make a stir in the mining world. The ledge in the tunnel is about three feet, and 14 assays were recently taken that showed an average of \$40 a ton. The tunnel is in nearly 200 feet, and there is considerable ore on the dump. As soon as the mill he is now building at Copper mountain is completed, Mr. Skewes intends to start in crushing ore.

Nevada.

THE NEW REDUCTION WORKS.—*Transcript*, June 17: The lead bath reduction works which recently began operations in the old Plaza foundry building, near the narrow gauge station at this city, give every promise of proving a practical success. Supt. Howe is gradually overcoming the obstacles that have presented themselves since the experimenting began, and hopes to be able shortly to announce that the process is an unqualified success. Encouraging results have been obtained so far.

POTOSI MINE.—*Grass Valley Union*, June 20: Progress is being made on the Potosi mine, on Gold Flat. The old shaft has been retimbered down to the water level. Timber is arriving for the new hoisting works. Two Pelton wheels are to be put in for hoisting and pumping. Water power will be used under a 300-foot pressure, which will be sufficient to work the mine to any depth. The old shaft is over 300 feet in depth, and it is expected to be found in reasonably good condition when the water is pumped out. Superintendent Skewes will push the work as fast as possible.

MINING ITEMS.—More rich rock was brought in from the California yesterday. The quartz showed well in free gold and gold bearing sulphurets. The

vein improves as the drift is extended. The new shaft of the Wyoming mine is down 35 feet and everything is working smoothly. Three shifts of men are engaged in the sinking.

ST. JOHN MINE.—The shaft of the St. John mine is being sunk for the 250-foot level, and the ledge continues large and the quartz of good quality. The old shaft and drifts have been straightened, and the mine is now in good working condition throughout. The company is figuring upon a mill, with a probability that one will be erected this season.

Placer.

MAYFLOWER.—*Mt. Messenger*, June 20: We learn that Oscar Jones is running the Mayflower drift gravel mine in Placer county. At a distance of 8000 feet from the tunnel mouth a shaft was raised for air. The channel has been worked nearly 2000 feet both up and down stream from the point where the lead was first tapped by the main tunnel. The company has nearly a mile of channel left on the upper end before reaching the Breese & Wheeler line. The Mayflower is paying largely.

Plumas.

NUCKET.—*Plumas National*, June 20: Thompson and Thomas picked up a \$90 piece in their diggings, one day this week, which goes to show that there are as good mines in Plumas to-day, as there ever were; all that is required is to go deeper and properly handle. We know of no better country for capital to invest than Plumas county.

Sierra.

THE THISTLE.—*Mt. Messenger*, June 20: We learn that the prospect tunnel in the Thistle shaft, below Gibsonville, is still being pushed ahead. At a distance of three hundred feet from the shaft, a prospect hole was sunk to bedrock, a distance of nine feet, and a good prospect obtained. It is said that the company will soon put in an electric plant for lighting the mine. Parties who had the contract to run the Excelsior Tunnel at Cedar Grove, gave up the contract because the rock was too hard for the price, \$9.50 a foot.

SEIKRA CITY.—Good news has reached town this week. The Buttes mine is about to be opened. Stephen Thomas, acting superintendent of the Buttes mine, has put a force of men at work to repair the flume that supplies the mills of the company with water. This flume is about seven miles long and was badly wrecked by the heavy snows of the hard winter. There are fine prospects of the town becoming lively this summer, as it is reported that four mills are to be erected this summer, namely: at the William Tell, Sierra Buttes, Buttes Saddle and Phoenix. The Chips mine is giving promise of becoming a very valuable property at no distant day. We hear that the company has a vein of good ore five to six feet wide. We hear of a ledge of good quartz near Middle Waters, which is now being prospected.

Tuolumne.

SHIPPING ORE.—*Union Democrat*, June 20: Mr. Hank Gale and associates report their mine, situated on the Milton road below Tuttle town, as looking exceedingly well. He is now shipping ore of good paying quality to the reduction works near Sonora, to determine accurately its character and value. More study should be given by our mining men to this point.

NEVADA

Washoe District.

YELLOW JACKET.—*Enterprise*, June 20: Shipping 100 tons of gold-bearing rock daily from the lower levels and 35 tons of silver ore from the upper levels, and doing general prospecting work.

OEST.—The owners are confident that they are developing a veritable bonanza. The Taylor mill is running steadily on Oest ore.

CHALLENGE CON.—The joint Confidence and Challenge north drift on the 200 level is now in 754 feet, the face shows quartz having no value. The joint Confidence and Challenge east crosscut on the 1000 level is out 24 feet, 12 having been made during the week; the face is in porphyry.

CON. IMPERIAL.—West crosscut No. 1 from the main north drift on the 300 level is out 10 feet. The face shows quartz having no value. East crosscut No. 2 on the 500 level is now out 60 feet. The face is in quartz having no value. We are still extracting some filings and hunches of ore of fair grade.

CROWN POINT.—The south lateral drift from the winze on the 300 level is out 25 feet; the face is in porphyry, clay and low-grade quartz. Have cleaned out and repaired where necessary 170 feet of the 500 level west crosscut, and have now completed to within ten feet of the face. The 1000 level east crosscut from the south lateral drift is out 170 feet; the face is in a mixture of porphyry and clay.

BELCHER.—The west crosscut from the south drift from No. 2 crosscut, 200 level, was run 25 feet through porphyry and quartz of low grade. Have started a raise 80 feet north of the crosscut from the lateral drift, which is up 24 feet. The top is in porphyry with a little quartz in it. The north drift from the main west crosscut from the shaft was advanced 30 feet; total length, 281 feet; the face is in porphyry and low-grade quartz. The 1500 level east crosscut is out 69 feet, having been extended 14 feet; face in quartz giving low-assays.

KENTUCK CON.—Have started an east crosscut from the south lateral drift from the east raise, 1000 level. Have run through and the face is still in quartz of low grade on the average, containing spots of ore. The raise from the south lateral drift, 950 level, is up 21 feet and the top is in quartz containing stringers of pay.

JUSTICE.—Shipped 161 tons and 515 pounds of ore to the mill, worth \$18 per ton as per battery assays.

SEG. BELCHER.—On the 600 level the west crosscut from the south lateral drift is out 132 feet. The face is in soft ground composed of porphyry and clay.

SIERRA NEVADA.—Have repaired the Kenosha tunnel a distance of 200 feet. The west crosscut on the 630 level from the northwest drift, 571 feet from the shaft, is out 551 feet, 35 feet having been made the past week.

HALE & NORCROSS.—On the 1400 level they have opened a station from the north winze below that level and have started north and south lateral drifts therefrom. The joint winze in No. 5 east crosscut on our south boundary has been extended 15 feet, making its total 45 feet. The bottom is quartz and porphyry. On the 1300 level the north lateral drift

was advanced 25 feet; making total distance from the station 120 feet. The south lateral drift from the station on this level was advanced 25 feet; making a total depth of 90 feet. Face in quartz and porphyry. Are making good progress sinking the main incline; it is now 40 feet below the 1500 level.

SCORPION.—The joint north drift on the 900 level of the Union shaft was advanced 25 feet, making its total distance 144 feet from the shaft; face in soft porphyry.

SAVAGE.—Hoisted 587 cars of ore from the 500, 750, 800, 900 and 1400 levels. Shipped to the Mexican mill 530½ tons and milled 500 tons; average battery assay, \$14.58. We have bullion on hand amounting to \$14,505. The E-street tunnel has been extended 22 feet, making a total distance of 722 feet; are getting out some pay ore in this tunnel. The west drift from this station, Potosi tunnel level, has been extended 32 feet, making its total 117 feet from the shaft. On the 750 level they are extracting ore of good quality. On the 950 level the south upraise has been carried up 85 feet. They are saving some ore from this upraise. On the 1100 level the north drift from the Hale & Norcross side was advanced 16 feet. This drift continues in quartz giving some fair assays. On the 1400 level have started east crosscut No. 2 from face of the north drift; face is in quartz and porphyry. The east winze on this level is down 28 feet; bottom in low-grade quartz.

UTAH.—725 level: Have continued cutting out the winze station at a point 140 feet below this level and are doing necessary repair work in the winze, which is in swelling ground.

POTOSI.—The winze is down 159 feet below the 1400 level; the bottom shows porphyry and streaks of quartz. The south lateral drift from the incline, 1100 level, is out 228 feet; face in porphyry and streaks of quartz.

CHOLLAR.—The joint winze in the east crosscut, 1400 level, is down 65 feet; the bottom is in quartz and porphyry. Extracted and sent to the mill 519 tons of ore, worth \$20.39 per ton, as per battery samples.

BULLION.—The 1300 level (Potosi) south drift is advanced 28 feet; total from north line, 127 feet; face in porphyry.

UNION SHAFT.—West drift from the shaft, 900 level, has been advanced during the week 51 feet; total distance, 420 feet, face in porphyry.

NEW YORK.—Northwest drift, 650 level, is out 240 feet; face in porphyry. North drift, 1100 level, is out north of shaft 543 feet; formation, quartz.

WARO SHAFT.—The south lateral drift from the 1800 station is out 98 feet; face in porphyry.

SILVER HILL.—The northwest drift from the winze below the 160 level is out 7 feet; face in quartz and porphyry yielding fair assays.

ANORE.—On the 420 level, during the week, north drift from east crosscut No. 2 was extended 20 feet in quartz giving low assays. East crosscut No. 3 from main north drift was advanced 18 feet; face in quartz and porphyry.

Bernice District.

LOOKING WELL.—*Reno Gazette* June 20: W. E. Van Reed and Edward Storm, of Bernice, Churchill county, are in town. They say the Antimony mines in that district are looking fine. The gentlemen say that the district is attracting the attention of Eastern capitalists, who are trying to buy an interest. Mr. Storm has shipped since May 1st 70 tons of the ore to San Francisco, and received for it from \$60 to \$70 per ton. It costs \$25 per ton to transport the ore from the mine to San Francisco. Of this it costs \$20 per ton for transportation to the railroad, a distance of 65 miles, and \$5 per ton from Lovelock to San Francisco. That leaves about \$40 per ton for mining and profit, which speaks well for the district.

Columbus District.

A BIG CONSOLIDATION.—*Walker Lake Bulletin*, June 17: The consolidation is just announced in London of the Candelaria Waterworks & Mining Co., the Princes Mining Co., the Georgene Mining Co., of New York, and the Holmes Mining Co., Nevada. The name of the new incorporation will be the Consolidated Candelaria Co., Limited. The directors are Sir Wyndham Knatchbull, Bart., Sir Edward Hulse, Capt. Chas. W. Hulse, H. J. Hulse and Col. Wm. J. Sutherland. The Doris syndicate continues to carry a heavy share in the properties, the interests of which are now joined.

Hawthorne District.

LAPANTA.—*Walker Lake Bulletin*, June 17: During the week the incline below the tunnel has been continued, the formation larger, showing considerable iron. Stopping above the tunnel and extending the northwest drift above the tunnel. In a raise above the slope above the east drift from the bottom of No. 6 incline have encountered an independent chute of \$90 gold ore, which runs in a southeasterly direction. Twenty tons were shipped to Kincaid mill this week.

PAMLILO.—Lessees still continue to extract gold ore from the stopes at the north end of mine. Main tunnel is being driven ahead. Shipping ore to mill this week.

CENTRAL.—Sinking the incline has been discontinued for the present and the drift on 75-foot level being extended. Stopping above this level still continues. The usual amount of ore being extracted.

MOUNTAIN KING.—Main tunnel still being extended; formation softer, indicating proximity to the ledge.

HARTFORD.—Still sinking on the ledge, the ore produced being about half lead ore and half \$50 gold ore, ledge about six inches wide in bottom.

BEACON.—The stopes from the incline still producing lead and silver ore.

GOLO BAR.—The south drift, Martinez tunnel level, has been extended during the week eight feet, showing nice ledge, and on Saturday very rich ore was struck.

CONFIDENCE.—Sinking incline on vein found west of canyon, the ledge about 2½ feet wide, carrying some silver, and looking very favorable for rich ore; formation softer.

FAIRMOUNT.—Main south drift extended eight feet during the week. Have commenced to open the stope above the drift, which shows from five to eight inches of 150 ounce ore with occasional hunches of ore running 800 ounces.

CHALLENGE.—Discontinued sinking for the present; now running main tunnel ahead past old shaft, following vein, which is looking well.

NEW YORK.—A tunnel has been started to intersect the vein, and the cut and tunnel have been ex-

tended about 20 feet, and the first ledge has already been cut, showing about 10 inches wide, the same carrying very fine lead and silver ore and some gold ore. The tunnel will be extended to cut the parallel vein when it is the intention to turn south and follow the vein into the bill with a level.

IDA.—Vein continues strong and stopes producing very well.

WAR EAGLE.—Taking ore from stopes and mine looking very well.

Tuscarora District.

NEVADA QUEEN.—*Times-Review*, June 19: South drift from Commonwealth east crosscut, 4th level, extended 12 feet in the vein.

NAVAJO.—The 350 stopes are improving, the grade continues high and the ore is getting wider. Sent 52 cars of ore to the concentrator.

DEL MONTE.—2d level: Joint east intermediate drift extended 20 feet, exposing low-grade ore.

COMMONWEALTH.—1st level: Ore hoisted, 20 cars; average assay, \$35 per ton. Will commence hoisting first-class ore this week. 4th level: East crosscut advanced 12 feet. North drift from east crosscut extended and timbered 9 feet in the vein, 2½ feet of ore in the face assaying from \$22.65 to \$70 per ton.

BELLE ISLE.—The stopes continue to look well and have yielded 20 cars of rich ore and 33 cars of second-class ore. Sent to Union mill 121½ tons of ore, assay value \$35.95 per ton.

NORTH COMMONWEALTH.—1st level: In the south end of stopes have cut into some very fine ore which looks very promising for another body of ore; now in six feet.

NORTH BELLE ISLE.—The stopes above the 400-foot level are showing much better in the last few days; hoisted 3 cars first-class and 72 cars second-class ore. Sent to the concentrator 211.41 tons of ore which yielded 24.4 tons of \$167.40 assay value.

ARIZONA.

PROGRESS IN VARIOUS DISTRICTS.—*Prescott Courier*, June 19: Bradshaw district is about 40 miles south of Prescott, in Bradshaw mountains, the elevation of which is from 5000 to 8000 feet. These mountains are tolerably well watered and timbered. Principal mines now being worked are the Tiger and Crowned King. The King is very rich in gold; the Tiger, in silver. A letter from a friend of ours at the Tiger enables us to give this information: Width of ledge in raise from the 300-foot level, five feet. In it is ore that assays 200 ounces to the ton. In the drift south of station, there are 14 inches of 250-ounce ore. In north drift, from bottom of winze, there are four inches of ore that yields 1,000 ounces of silver to the ton. The drift is all in quartz, carrying high-grade metal. Not a bit of country rock in face of drift. It is scarcely necessary to say that all who are in any way connected with the mine are in good spirits. The Crowned King, a little east of the Tiger, is, as we said before, a large and rich gold vein. N. C. Shokels is managing operations at mill and mine, and doing it well. He is saving more gold, by mill process, than ever before, and making richer concentrates.

MONTANA.

PLACERS.—*Mining Journal*, June 17: The recent rains have inspired the placer miners to renewed activity. From all districts come favorable reports showing all possible advantage is being taken of the water supply. M. A. Tullock brought in 13½ ounces, the result of a seven day's run, with two men, which brought \$18 per ounce. Every available water-right is being utilized and the result will be that the placer cleanup for the season in Montana will run into the millions.

IDA MINE.—E. A. Beattie left Helena last evening wearing his mining boots, presumably enroute to the Ida mines in the Boulder valley, it being reported that a good strike has been made.

YORK GULCH.—T. H. Pratt is working the placers of York gulch, across the Missouri river, under lease from the owners, the plentiful water supply giving promise of a good cleanup.

HOMESTAKE.—Mr. Jewell has returned from a visit to the Stemple district, bringing in a substantial and satisfactory gold brick, the result of the first cleanup of the Homestake mill.

SNOW AND PLACERS.—The clouds have had another output of the placer miner's best friend, snow. Miners in from the Upper Cataract Basin district report fully a foot of snow having fallen the past three days and the end is not yet. Already the first cleanups are coming in, and the sight of an old huckskin well filled brings encouragement to the hearts of all.

NEW MEXICO.

HANOVER.—*Southwest Sentinel*, June 20: The approaching advent of the railroad into Hanover has already imparted a stimulus into that somewhat neglected camp, and now it would be difficult for the prospector to find a vacant space in the whole mineral belt available for the erection of an initial monument. When the construction of the road was first mooted mining men foresaw the possibility of realizing a small net profit over expenses on the low-grade products of the camp, when the reduction of freight comes into operation, and accordingly appropriated all the old abandoned prospect holes showing copper lead or iron. The railroad grade is completed to within two miles of the terminal point specified in the present contract. Worthen & Wake are delivering ties in compliance with their agreement, and at an early date the road will be in running order. The Neff copper mine, under the able management of I. C. Johnson, is producing large quantities of ore, and as soon as the new hoiler is fixed in place the smelter will have an abundance of ore to keep it running continuously. Mr. Neff has handed a number of iron and copper mines containing immense bodies of metal. The figures amount to quite a plethoric sum for the group and, if the sale be consummated, Jack Shanley and others will be handsomely remunerated for some years of patient toil. The zinc mines are producing as largely as ever, but the Zinc Valley mine has proved to be the great bonanza of the lot, and shows no diminishing feature in its vast ore bodies. An expert examined the great deposits of white and variegated marble a few days ago. He pronounced the quantity inexhaustible and the quality equal to the finest Italian.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JUNE 16, 1891.

- 454,195.—VENTILATOR—P. Abrahamson, S. F.
 454,105.—TAG AND PARCEL TIE—W. H. Anderson, Riverside, Cal.
 454,199.—RIVETING MACHINE—M. Arnold, S. F.
 454,202.—SAFETY GUARD FOR SLEEPING CARS—Nathan Brown, Oakland, Cal.
 454,206.—STEAM GANG-PLOW—N. L. Darling, Benicia, Cal.
 454,033.—BURGLAR ALARM—C. C. Davis, Los Angeles, Cal.
 454,340.—FILTER—J. A. Fulton, Astoria, Or.
 454,213.—AXLE-SETTING MACHINE—G. W. Hunter, Fresno, Cal.
 454,218.—GOVERNOR—J. F. Kirby, S. F.
 454,219.—WRENCH—H. H. Love, Sacramento, Cal.
 454,220.—RULING PEN—H. H. Love, Sacramento, Cal.
 454,221.—WRITING PEN ATTACHMENT—David Lubin, Sacramento, Cal.
 454,180.—PUMP—W. McLennan, Port Angeles, Wash.
 454,225.—HARVESTER—J. & W. Paterson, Stockton, Cal.
 454,226.—WALL FIXTURE FOR ELECTRICAL CONDUCTORS—Pieper & Watson, San Jose, Cal.
 454,228.—ROCK DRILL—E. A. Rix, S. F.
 454,230.—THRASHER—E. F. Sanford, Merced, Cal.
 454,235.—CABLE RAILWAY GRIP—J. C. H. Stut, S. F.
 454,238.—ELECTRIC POLE IN GAS OR VAPOR EXPLOSIVE ENGINES—Tremper & Eisenbuth, S. F.

The following brief list, by telegraph, for June 10 will appear more complete upon receipt of mail advices: California—Ulrich Bachmann, San Francisco, fermenting vat; Willis G. Dodd, San Francisco, water-wheel bucket; Carl A. Erlandson, San Francisco, saw setting and filing machine; Henry P. Holland, assignor to J. A. Fisher, San Francisco, wave-power motor; Louis M. Howe Greenwood and L. A. Gates, assignors to H. J. Postel, San Francisco, apparatus for extracting gold and silver from ores; Frederick Lampert, San Francisco, assignor to A. J. Levanke, Tacoma, Wash., coating for piles, etc.; Benjamin Marshall, assignor to Marshall Improved Window Furniture Company, San Francisco, sash balance; Walter N. Sherman, Merced, electrical pessary. Washington—George Brown, Waltsburg, pump. Arizona—Dudley I. Craig, Silver King, adding machines.

Notes.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

WRITING-PEN ATTACHMENT.—David Lubin, Sacramento. No. 454,221. Dated June 16, 1891. This invention consists essentially, in the application to the pen of supporting or guiding arms which project downwardly beneath the pen-holder at a point sufficiently behind the nib of the pen, so that these arms will rest upon the surface of the paper and form with the pen-point a triangular support, which will relieve the wrist and fingers from strain, will hold the pen at a constant angle with the paper, and enable those who have unsteady nerves to write steadily. In writing, the point of the pen is moved over the paper in the usual manner, and the attachment or arms steady it while not presenting any obstruction to its free movement over the paper. These arms may be made rigid or slightly flexible, so as to yield under the natural pressure of the hand, and are made adjustable so that the user may set the point of the pen at any desired angle with the paper. By means of the clamp the pen may also be turned, if desired to suit the requirements of the writer.

HARVESTER.—James and William Patterson, Stockton, assignors to the Benicia Agricultural Works. No. 454,225. Dated June 16, 1891. The construction of this machine is such that, as the thrashing and cleaning machinery is supported upon and by the bearing wheels of the traction engine which propels the machine about the field and at the same time furnishes power to drive the machinery, no provision need be made for any irregularities of movement caused by traveling over uneven ground; and as the beader by which the grain is cut is hinged to the front of this rigid frame, so that the hinges are in line with the shaft by which power is transmitted from the engine to the header and the various moving parts dependent upon it, the sickle may be raised and lowered to suit the height of the grain, which is being cut, by any of the usual appliances for this purpose without in any way disturbing the connections. The whole machine may thus be supported, propelled, and operated from the single set of wheels which carry the traction engine.

SAFETY GUARD FOR SLEEPING CARS.—Nathan Brown, Oakland. No. 454,202. Dated June 16, 1891. This safety-guard for sleeping car berths is specially applicable to the upper berths for the purpose of preventing the occupants from falling out by reason of the swaying of the cars or from other causes. It consists of an adjustable webbing or net, with a means for applying it or packing it out of the way. The guard is a permanent attachment to the berth and is readily adjusted for use or rolled out of the way.

WALL FIXTURES FOR ELECTRICAL CONDUCTORS.—Oscar H. Rieper and Frank M. Watson, San Jose. No. 454,226. Dated June 16, 1891. This is a device which the inventors call a wall fixture for electrical conductors and it consists of a means for more accurately and rigidly fixing said conductors at points where they pass through plaster walls or other supports. In running electrical wires through buildings it is customary to bring the wires through the walls at such points as are necessary without regard to the proximity of a stud or other

firm support and the caps within which the electric buttons are contained are fastened by screws which often only enter plaster and the whole of the attachment is thus so loose that they frequently become detached and the wires are apt to become deranged. This wall fixture covered by the patent gives a firm support to the wires so that they are not likely to be pulled from their places or disturbed and prevents any ingress of mice or other vermin through the openings which may be made for the passage of the wires.

CABLE RAILWAY GRIP.—J. C. H. Stut, S. F. No. 454,235. Dated June 16, 1891. This cable-grip consists in certain improvements whereby the grip may be released from the cable for the purpose of stopping the car without dropping the cable, while at the same time retaining that construction which allows the cable to be dropped directly, in case of necessity, from the bottom of the grip. A grip of this kind is technically known as the "bottom" or "center grip" in distinction from that class of grips which the cable is removed from the sides of the grip, and which are known as "side-grips." This invention is designed to combine the valuable features of that class of grips known as "bottom and side grips" and to overcome the objectionable features of both these forms of grip. In what is known as the "bottom" grip the jaws open and close horizontally or nearly so, and when the cable is released it drops directly downward below the grip and but little space can be allowed for the movement of the jaws. By reason, however, of the compression upon the sides of the cable the latter is pressed into an oval section and by reason of the wear upon the dies which form the jaws of the grip, the lower edges of the dies soon become so sharp as to greatly injure the cable when the grip is slightly released from the cable while running. In what is known as the "side-grip," pressure is also applied on two sides, which flattens the cable and shortens its life. The upper vertically-moving jaw closes and uncloses upon the cable, and when it is opened for the purpose of releasing the cable the latter has the support of the lower jaw while it is traveling, but when it is to be entirely released from the grip considerable space must be allowed for the grip to move to one side for this purpose, and it is more difficult to pick up the cable after it has been released when this form of grip is used. The distance between the dies of the grip and the center line of the cable in its ordinary course on the carrier sheaves is also considerable more with these grips, because the lower die, with its support, has to clear the carrier pulleys in traveling. In this improved grip one or more jaws close upon the cable from above, and the gripping surfaces are approximately evenly spaced, so that radial pressure is brought upon the cable from three or more directions, and the cable is so nearly enclosed by the dies that it is not pressed out of shape by the strongest pressure.

ELECTRIC POLE IN GAS OR VAPOR EXPLOSIVE ENGINES.—Frank E. Tremper and John W. Eisenbuth, S. F., said Eisenbuth assignor to Electric Vapor Engine Co., same place. No. 454,238. Dated June 16, 1891. The invention consists in the novel construction and arrangement of the electrodes by which the electric spark is made for exploding the charge of gas within the cylinder. The object is to provide simple and durable electrodes for this class of engines. The electrodes are rigid bars or rods, and are more advantageous than the usual elastic or spring form which soon wear out and have their temper destroyed; but the necessary yielding of the rigid electrodes before the stroke of the piston is obtained by springs which control the sliding of the electrodes, allow them to yield and throw them back to place as soon as the pressure upon them is relieved. The manner of mounting them is simple and convenient, permitting their ready removal and insertion.

ROCK-DRILL.—Edward A. Rix, S. F. No. 454,228. Dated June 16, 1891. The invention relates to rock-drills of that class in which the drill is connected with a piston working in a cylinder under air-pressure and in which the valve mechanism is so arranged that the reciprocation of the drill will be produced automatically. The present invention has for its object an improved arrangement of valves and valve gear consisting of a main valve, a transversely moving and independent supplemental valve, with a stud engaging a cam groove upon the main piston by which it is actuated, and an exhaust valve common to the main and supplemental valves, also in a spirally grooved drill rod, a drill head having radial slant flaps, moving to these slots and engaging the teeth of a ratchet disk, and holding springs, by which the drill is rotated as it is reciprocated.

RIVETING MACHINE.—Matthew Arnold, S. F. No. 454,199. Dated June 16, 1891. This machine is used to rivet leather-belts, boot-straps and other articles, and consists of a feed chute peculiarly arranged to deliver the rivets in the proper position, a vertically moving guide and plunger by which the rivets are formed into the fabric to be riveted, a slide moving transversely to transfer the rivets to a point beneath the plunger, stops so operated as to arrest the rivets at certain points and allow them to move successively from one point to another, an upwardly moving anvil upon which the rivets are headed, a driver to deliver washers which fit the rivets and are secured by the punch and anvil, and mechanism by which these drivers are all actuated at the proper time with relation to each other to produce the required results with accuracy.

AXLE-SETTING MACHINE.—Geo. W. Hueter, Fresno. No. 454,213. Dated June 16, 1891. This invention relates generally to the class of machines for manipulating metal bars of all kinds to be bent or straightened them as may be desired and especially to those devices used for taking the bends out of vehicle axles. With this machine the axle may be adjusted without taking the axle from its connections with the vehicle. This machine has power enough to straighten any axle and an ordinary wrench or lever may be used to turn the nuts and screws. The work does not have to be bent or the axle taken off the vehicle. The whole machine is a simple and durable one for the purpose.

GOVERNOR.—John F. Kirby, S. F. No. 454,218. Dated June 16, 1891. This is one of that class of governors adapted to regulate the valves of the engine according to, and by means of, steam pressure. It consists of a cylinder communicating with the

steam pipe and baving within it a spring-controlled piston with projecting rod, a second cylinder having a spring-controlled piston and piston rod, the latter being adapted to come in contact with the piston rod of the first cylinder whereby it is moved, a suitable connection between the piston rod of the second cylinder and the engine valves, a valve aperture in the piston of said second cylinder and liquid in said cylinder to control the return of its piston.

THRASHER.—Edgar F. Stanford, Merced. No. 454,230. Dated June 16, 1891. This invention relates especially to traveling thrashers and to such thrashers as are united with heading machines and known as "combined harvesters." The chief improvement lies in a confined vertical open-ended passage directly below the grated concave. Into this passage such grain as is separated in the concave, and such as is separated on the carriers and returned, falls. A fan blower creates a blast of air, which is divided by a directing board, so that one portion of it passes above the open top of the vertical passage and across the path of the falling material thus blowing away the chaff; another portion passes directly upwardly through the passage, thereby suspending the chaff and holding it up to the action of the cross current, while the grain drops through of its own weight; a third portion passes under the passage and blows away whatever chaff may fall through with the grain. Other improvements consist in a simple means for strengthening the frame by the rods, and in the driving mechanism; which avoids all strain and can be readily taken apart for repairs.

STEAM GANG-PLOW.—N. L. Darling, Benicia, assignor to Benicia Agricultural Works. No. 454,206. Dated June 16, 1891. This steam gang plow consists essentially of a main frame with means for connecting it with a traction engine and means for connecting with said frame as many gangs of plows as it may be desired to haul. Upon the frame a roller is placed and adapted to travel freely up and down within a slotted yoke, allowing the plows, and the frame-work to move with relation to each other and accommodate themselves to variations in the surface of the ground without forcing the plows too deeply into the ground at one time or throwing them out of the ground at another. This construction is extremely important where so many gangs of plows are being hauled by the single framework and where it would be impossible to otherwise regulate all of the plows to make them do proper work.

WRENCH.—Harry H. Love, Sacramento. No. 454,219. Dated June 16, 1891. This is a socket wrench and consists of two independent bars, adapted to slide over each other, carrying one-half the socket which clamps the nut, a means for locking these plates together at any desired point, so as to form a nut socket of any size, and certain details of construction. As the wrench clamps the opposite corners of the nut, it will be manifest that the nut will not be liable to have its corners twisted off, or marred by any power that can be applied to the wrench; and as the sockets are turned at right angles with the intervening shank or handle, they may be fitted over nuts which are otherwise out of reach.

RULING-PEN.—Harry H. Love, Sacramento. No. 454,220. Dated June 16, 1891. This ruling-pen is specially applicable for the use of book-keepers. It consists of a pen having points so made that it is adapted to make either double or single lines. By the use of this pen the double lines used in book-keeping are all symmetrical, and both double and single lines can be made much more rapidly than with ordinary pens.

Our Agents.

Mining Share Market.

As indicated in last week's PRESS, mining shares shaded off under cross orders. At the declining prices the pool added largely to their already heavy holdings. They will undoubtedly cause prices to sink as low as possible under a very sick looking market, so as to get if they can, more stocks; for stocks they are after, and stocks they will have, if low prices, bear points and a heavy, sick looking market will cause outside selling. In well informed stock circles it is asserted that the pool has from 75 to 90 per cent of the shares of the 26 mines that are pooled for the big deal this Fall, when prices are to go from 10 to 30 times higher than they sold at, on yesterday (Wednesday) or in other words the person who buys more and pays cash, will make from \$10 to \$30 on each and every dollar he invests; but if a buyer purchases more than he can pay for and has his broker to carry the stock on a margin, he is liable, under an inside bear raid to lose all. It is overhanging that ruins outside operators.

Never within the history of the Comstock mines was there a more favorable time to start a market. The dead-work done in the mines has been on an immense scale. They are honey-combed with drifts and crosscuts, run to open up several levels before showing up in one or more mines a large body of rich ore, with, in the others, small but rich lodes of considerable depth. This dead-work the public paid for in assessments, and tiring of the business just when the pool is ready for a large sized deal, if not a market, they have sold out at heavy losses—the pool buying. The ventilation and connections in the various mines, were over so perfect as now, while the mills for crushing ore have been overhauled and put to the very best condition for a long run. Aside from the favorable condition of the mines, the financial and general conditions throughout the United States favor a big bull campaign. The crops are large and good prices assured; the laboring classes are generally employed and are fairly prosperous; the poor grain crops in Europe assures to the United States large customers for our surplus; thereby causing all the gold sent from here and more besides, to return. The London *Statist*, which is considered the best of authority, says, that France alone will send to the United States over \$50,000,000 in gold to pay for wheat, while England and Germany will send a still larger sum. Aside from this, our large crops and increased railroad freights will enable United States railroad companies to make splendid returns; these returns will cause European speculators to buy American railway securities, and to pay for them, metallic money will have to be remitted. All this insures a plethora of money this Fall. To this must be added a certainty in the price of silver reaching about par before Congress meets. This advance will be brought about by the discussion of free coinage and the advanced stand taken in its favor by farmers through the Grange and Alliance, and the wage earners through their national organization. Everything points to a large upward movement this Fall, if not sooner.

The market opened this (Thursday) moving active and higher with, Con. Virginia the leader. Chippers and others claim that prices will go off again, and that in July the markets will be a buy for the big deal in the Fall.

Comstock mining news not only confirms last week's advice, but adds that the development in Con. Virginia, on the 1750-foot level, is much more important than heretofore claimed. It is enlarging and getting richer. In Hale & Norcross it looks as if they are opening up a veritable bonanza. In two of the Gold Hill mines that will probably be assessed soon, they are developing something of unusual importance. It is not likely the assessments will cause well informed outsiders to sell, as the pool desires.

On May 25th, the official records of the Con. Virginia office report the bullion returns for May amount to that date at \$51,185, and for this month (June) show that the bullion returns to the 24th were \$104,279, a gain so far in this month of nearly \$53,000 over the like time in May; and yet it is not certain if the company will pay a dividend in July. There are those who claim that the funds will be allowed to accumulate so the company can start in on \$1 dividends. The net surplus in June will be about \$350,000.

A suit against the West Con. Virginia officials has been commenced by a Mr. Steel, who alleges fraud and conspiracy in certain stock transactions. The parties against whom the suit is brought have been prominently identified in the fight against the mill ring, stock pool and mine mafias.

The pumps in the Gover mine, Amador county, are now operated by electric power. It costs \$5 per day as against a cost for wood alone, with steam pumping of \$20 to \$30 a day.

MECHANICAL PROGRESS

Phenomenal Friction.

As the subject of friction is one which is just now attracting much attention among mechanical engineers, the following result of some experiments recently made by Mr. J. H. Cooper Jr. of the Franklin Institute may be considered of more than mere passing interest:

When making experiments, during the month of February, 1891, with the Thurston railroad testing machine, I noticed the ease with which the axle-hox could be made to slide longitudinally upon the axle when the same was in motion.

The several hoxes tried had about 14 square inches of surface in contact with the axle; they were variously loaded, with weight from 262 pounds upward, and the axle was running at speeds varying from 160 to 400 revolutions per minute. One hox could be moved by a pressure of one ounce when the axle was running, but required 32 pounds to move it when the axle was still.

Another hox was moved by four ounces with motion, but required 40 pounds without motion of the axle. A third hox under considerable pressure could be moved readily by a pull of six ounces, but 50 pounds would not start it when the axle was still, and, indeed, on trial, all the muscular force I could apply to it by my hands, with my foot against the machine, failed to start it. A spring balance was used in these experiments, for pulling the hox in a line parallel to the axle.

Here we employ forces anywhere from 160 to 1, up to perhaps 1000 to 1, for moving the same body, under the same load and conditions, except that of the revolving or standing shaft beneath it. This phenomenon of friction proved a marvel to all who witnessed it. The temptation was great to theorize upon this extraordinary performance, but no theory was offered in explanation of it. A practical suggestion was made, however, in reference to planer-hed motions, and the like, which drag so heavily upon their fixed ways. If, as then proposed, revolving shafts were placed in the hed ways, and the table fitted to them, a pound pressure would move the table and its load back and forth on the revolving ways, where 1000 pounds or more would be required to do this work on the usual fixed V's or planers, as they are generally built. To the writer, this unique action, as if the loaded hox were floating, was an instructive object lesson in mechanics.

WHY DOES SOLID IRON FLOAT ON MOLTEN IRON?—This question, which has puzzled a good many observers, was satisfactorily explained by Dr. Anderson in a recent paper on steel read before the Iron Institute, London. When a piece of solid iron is thrown into a pot of molten iron or steel, the solid metal at first sinks, which shows that its volume is less than the melted metal. But soon the solid piece becomes heated, which causes it to expand, its volume is increased, and it rises and floats on the surface of the molten mass. The action is the same both with iron and steel. Mr. Wrightson said: "The experiment was frequently made by throwing a piece of iron into melted steel. They could see it go down, and might think that it was on account of the impetus which the iron had attained in falling that high, but as a matter of fact, if the iron had attained in falling that high, but as a matter of fact, if the iron were put upon a fork and lowered, it would go down; but in the course of a few seconds it came up again, and kept on expanding until the piece of iron was a considerable distance above the surface of the metal. Then it decreased in volume, and of course became of the same volume as the molten metal which it joined. Any one could see by the distance that the piece of iron went above the surface that it was of considerably less density than the molten metal."

WHERE THE IRON GROWS—In the city of New York there are about 500 miles of paved streets, and it is estimated that there is in constant wear upon these streets about one million tons of iron, in the shape of wheel tires, street car rails, horseshoes, etc.; not more than one-half of which ever gets back to the puddling furnace or rolling mill. Tons of iron are worn off from horseshoes every day, perhaps 20 times the amount is lost from tires of ordinary vehicles. The surface roads give off tons from the rails and car wheels; the elevated roads also lose tons from their rails and car wheels. The pedestrians grind off tons of nails in the heels of their shoes, and not an ounce of all this is saved. It becomes dust and is blown everywhere, but the great majority finds its way to the head of the ocean with street dirt and garbage, and until some great revelation shall make a radical change in ethereal matters the millions of tons of iron which are thus deposited in the wild waste of waters will not again enter into the useful arts of which they were once such an important factor.

CHECKED COMBUSTION.—"The result of checking combustion is fully as uneconomical as that of incomplete combustion. In the combustion of ordinary coal gas, as when used in the gas range, a great deal of the unconsumed gas escapes, as is shown by the odor that may be noticed in the room. In this case the combustion is checked by the flame striking

the cold surface of whatever it may be on the fire at the time. This cooling down of the gases prevents the full combination taking place, because the combination requires time as well as temperature to become fully complete. The same thing takes place in the boiler furnace where, although the gases and air may be mixed in the correct proportions for complete combustion, yet this cooling down of the gases from striking the cooler surface of the boiler checks the combustion at that point and the different gases are delivered to the atmosphere uncombined after having passed through the boiler tubes. The amount of heat-producing matter thus wasted is the most important factor in such cases, but where gas is used for cooking and lighting purposes the gases which escape are deleterious to health. This is a subject of considerable importance at the present time, when gas stoves and ranges are being so largely introduced."—*Stationary Engineer.*

IRON AND STEEL FORGINGS.—According to an invention by H. E.hardt, of Dosseldorf, Germany, hollow forgings in iron or steel are made from solid blocks of red hot or white hot iron or steel. Several examples of the process are described, from which the following are selected: To produce a hollow cylinder a piece of hot square metal is taken, the cross-section of which, diagonally measured, corresponds to the diameter of the hollow cylinder to be produced, and a pointed core bar is then driven into the metal by means of a hammer or press, the lid of the matrix forming a guide for the core bar. When desired, the matrices may be formed with jackets in which circulates a cooling medium. The metal is thus forced to fill the cylindrical matrix, and has an opening through its centre in the direction of its length. Hollow prismatic bodies may be produced in similar fashion, an important condition in all cases being that the metal to be operated upon shall be truly centred by the matrix. For hollow bodies of unusual length two core bars may be employed, entered into the metal from opposite ends. Where steam hammers or presses are used, their frames may form guides for the matrix.

A FOOTCH INVENTOR makes a solid round hand of rope, for power transmission, by imitating flat webs of canvas or other fabrics with a solution of gutta-percha, rolling it upon itself, and wrapping with cloth. A flat web is made in a similar manner by folding the fabric into layers of the desired width and passing it through pressure roll. Why, asks the *Sewing Machine News*, cannot some of those who are connected with the manufacture of sewing machine supplies take a hint from what this Scotch inventor has done, and bring out a material for sewing machine belts to take the place of the leather belt that is now in use? Could not a woven chord be so combined with gutta-percha or similar material that would produce a cheap as well as a durable belt?—*Invention.*

A FOUNDRY HINT.—When cores run through heavy bodies of iron, the hot liquid raises the feeble element of the sand to such a high temperature that the grains fuse together, so that when the casting cleaner tries to get the core out he finds it almost as hard as the iron. A good thing to prevent this fusing of the sand is to mix some sea coal or blacking in it and to give the surface of the core a good body of black lead or plumbeous blacking. The outside coat of blacking will prevent the liquid iron from eating into the surface of the core sand, and the sea coal or blacking, mixed in the sand burns away and partakes of the forms of gas, leaving a porous body between the grains of sand, which assist in preventing its fusing.—*Invention.*

INVENTION.—A Western manufacturer, whose manufactures are covered by several patents, expressed himself recently to the writer to the effect that he had never really invented anything; that he had simply combined things to his purpose, and nothing more. All of this shows a misunderstanding of what is really meant by the expression "to invent." No one can invent the sunshine, but it is possible for any one to invent uses for the sunshine, and to obtain a patent on so doing. Then he will bear a lot of criticism, because the sun shone before he was born.—*Am. Machinist.*

SCORING IN BEARINGS is likely to occur where there is no end-way movement or at least this is one of the reasons why such movement is recommended; but there are places where the least endway movement is not allowed, and places too that have all they can manage, especially where level gears are used. On long lines of shafting, where expansion causes a movement in every hanger, there must be a fine chance for some of the bearings to get a new seat almost any portion of the day.

MOULDS FOR CASTING IRON can only be made in sand. Iron or other metallic moulds chill the iron, and it does not fill well. The great heat at which iron melts will burn any other material, or will stick so as to break the mould.

FOUR FIFTHS of the engines, including locomotive engines, now working in the world, have been constructed during the last 25 years, and represent a grand total of 49,000,000 horse power.

SCIENTIFIC PROGRESS

A Cosmical Telephone.

We have already made brief reference to the attempt which Mr. Edison is making to catch the echo of sounds from the sun. He calls the device a "cosmical telephone." The "wizard" owns an iron mine in the town of Ogden, New Jersey, which consists of a bed of magnetic iron ore about a mile long and 450 feet wide, which he thinks runs down into the earth for five or six miles.

As would naturally be inferred, there is an enormous intensification of magnetic forces at that locality. Careful observations at the Kew Observatory, near London, have shown that such magnetic forces, wherever they exist, are directly influenced by the disturbances in our luminary known as sun-spots.

Mr. Edison says that at his iron mine he will have a million times the concentration of magnetic lines that there is at Kew. To record the daily variations in his own magnetic lines at Ogden, Mr. Edison is constructing his cosmical telephone.

"There are the most wonderful things going on in the sun's spots all the time," he says. "The disturbances are tremendous. Bursts of hydrogen fly out of these spots 600,000 miles long."

To construct his telephone he has surrounded the whole bed of magnetic iron with telegraph poles. On these poles he is stringing a cable of 15 copper wires. The ends of this cable run down into a little house and are connected with the ordinary receiver of a common Bell telephone. The idea is that the surrounding of this enormous bed of magnetic iron with the copper wires will make it a gigantic magnet such as is used in the receiver of the every-day telephone. Through this tremendous receiver Edison says he will be put in direct telephonic communication with the sun, only the communication will be one-sided. He thinks he can hear something of what is going on up there, but he can't do any transmitting. He believes that every disturbance resulting in sun-spots are attended with loud detonations and that they will cause a corresponding variation of the concentrated magnetic lines at Ogden, and that this variation will be at once detected in some way by the receiver of his cosmical telephone.

"Yes, sir," he says, "I shall bear them with this telephone. The next time there is a violent change in the sun's spots which disturbs the magnetic lines on earth I shall know it, and if 600,000 miles of hydrogen go chasing away from the sun I shall bear it."

The cosmical telephone is not yet completed, but scientific people other than Mr. Edison will watch with curious wonder to see what success he will achieve.

AGRICULTURAL SCIENCE—THE ORIGIN AND USES OF HUMUS.—Mr. Neel of Florida, says an exchange, is deeply interested in science applied to farming. We write this especially for his consideration. When the putrefaction of dead plants is completed, there remains a soft black mass, known as vegetable mold or humus. One hundred parts of the humus of wheat straw contains 26 parts of boric acid; the remainder is lime, peroxide of iron, phosphate of lime and carbonaceous matter. This boric acid contains carbon 47 parts, hydrogen 20 parts, oxygen 33 parts. Chemical action in the soil converts part of this into carbonic acid which is absorbed by the roots of plants as part of their food, while the phosphates, potash and other simples have their effect in dissolving the inert principles in the soil, independent of the humus, reducing the whole to plant food. Of course, when we speak of any acid or any alkali in the soil as having destructive action on mineral, animal or vegetable substances, we understand them to be in a very diluted form. We all know that acids and alkalis in their commercial forms are among the most powerful destructive agents known. The operations of nature, especially in promoting vegetable growth, are toned down to suit the tender, delicate nature of the tissues to be acted upon. In the rise and growth and in the fall and decay of vegetation there is no violence, the reduction of animal tissue and the extraction of mineral properties from soils and rocks is very gentle.

WHY SNOW IS WHITE.—The pure white luster of snow is due to the fact that all the elementary colors of light are blended together in the radiance that is thrown off from the surface of the crystals. It is quite possible to examine the individual snow crystals in such a way as to detect these several colors before they are mingled together to constitute the compound impression of whiteness upon the eye. The snow is then clothed with all the varied hues of the rainbow. The soft whiteness of the snow is also in some degree referable to the large quantity of air which is entangled amid the frozen particles. Snow is composed of a great number of minute crystals. More than a thousand distinct forms of snow crystals have been enumerated by various observers. One hundred and fifty-one were noticed during eight days in February and March, 1855, by Mr. Glaisher, which were carefully drawn, engraved and printed in a paper attached to the report of the British Meteorological Society for that year. These minute crystals and prisms reflect all the com-

posed rays of which white light consists. Sheets of snow on the ground are known to reflect beautiful pink and blue tints under certain angles of sunshine, and to fling back so much light as to be painful to the eyes by day, and to guide the traveler, in the absence of moonshine, by night.

LIGHT AND HEAT.—Light has been defined as any effect on the sense of sight—a sensation due to the mechanical effort produced upon the extension of the optic nerve, which forms the sensitive surface of the retina. Such mechanical action must have a mechanical cause, and as far as can be judged with the present knowledge the cause must consist of impacts on the retina, due to moving matter. This matter may have traveled all the way from the source of light, or it may have been set in motion in the eye by a disturbance which has traveled from the source. As far as can be conceived light must consist in the motion of particles of some kind from external objects to the eye, or in the propagation of some disturbance or wave motion in an as yet unknown medium. Heat is a property of matter known by one of six very distinct senses. Man has no definite idea as to the nature of heat—whether it is a subtle elastic fluid or a state of motion, or, possibly, some modification of matter related to action of force. The only hypothesis that at all accords with the phenomena of the materiality of heat is that it is a form of motion.—*Ex.*

A CURIOUS INSTRUMENT.—A very useful kind of instrument, according to the description given in the *Paris Genie Civil*, is the ergatoscope, designed lately by M. Trowe, and intended for the convenient and accurate examination of geological strata pierced by deep boring. The apparatus is entirely simple, consisting of a powerful electric incandescent lamp, enclosed in a cylindrical case, one of whose curved sides serves as a reflector, and the other, made of thick glass, permits the illumination of the bore hole. An elliptical mirror, set at an inclination of 45 degrees in the bottom of the case, throws its images vertically upward through the open top of the case to the observer, who examines them through a powerful telescope. It is said that the apparatus works satisfactorily to a depth of 1000 feet, and that the Portuguese Government has applied it to its expedition that is exploring the abodes of Mozambique.

AGE OF THE GLACIAL PERIOD.—In discussing the cause of the glacial period, Mr. Warren Upham discards the astronomical theory, since it seems wholly untenable in view of the geologic evidences that not many thousands of years have passed since the departure of the ice sheets. The measurement of the gorge and falls of St. Anthony, the surveys of Niagara Falls, the rates of wave cutting along the sides of Lake Michigan, the rates of filling of kettle holes, and the rate of deposition in the Connecticut valley at Northampton, Mass., all indicate that the time since the glacial period cannot exceed 10,000 years. Mr. Upham cites evidence in proof of the theory that the cause of the glacial period was great uplifts of the glacial areas, probably in conjunction with important changes in the course and volume of the warm ocean currents.—*Am. Geol.*

SUBMARINE DISCOVERY.—Divers in the harbor of ancient Syracuse have discovered a magnificent marble building, whose highest point is only three metres under the water. The building contains great stairways and colonnaded halls. It is believed that the edifice was once used as a bath or a temple.

A PHOTOGRAPHER in Pennsylvania obtained a negative of the bottom of an oil-well in which had been exploded a glycerine torpedo. The instrument was lowered 1700 feet, and illuminated with an electric flashlight, the result being a distinct picture of a curious cavity in the earth 14 feet long and 7 feet deep.

ARTIFICIAL MALACHITE.—A material closely imitating malachite is made by precipitating a solution of cupric sulphate of potassium or sodium carbonate. When the precipitate has settled and cohered, it is dried with gentle heat, and may then be cut and given a beautiful polish.

A NEW SEWING MACHINE, invented by a Mr. Jones, of Cardiff, Wales, has no shuttle or bobbin. The thread is supplied directly from two ordinary spools and sews through the assistance of a rotary looper. It is vastly more simple than any other sewing machine.

THE FUTURE OF CHEMISTRY.—The chemist will dominate coming inventions. All our fuel will presently be furnished in the form of gas. In a quarter of a century more, we shall wonder why man was ever such a fool as to carry coal into the house and burn it.

THE BAROMETER AND EARTHQUAKES.—The idea that a connection exists between an earthquake shock and the height of the barometer has been proved to be incorrect. This statement is based on the observations of 531 earthquakes recorded in Japan.

THE EARLIEST WEATHER RECORD.—The first known weather record was kept by Walter Meric for the years 1337 to 1344. A few photographic copies of the original satin manuscript, now in the Bodleian Library, have just been made.

GOOD HEALTH

The Physician as a Despot.

Without any pretense of faith in any doctor who is not regular, and without prejudice to a sincere intention of calling in a thoroughly instructed and expert practitioner whenever occasion demands, it is still permissible to smile amiably at the professional jealousy of quacks. The successful physician, with exceptions which happily are much more numerous than they were, is the most intolerant despot on earth, and we encourage him to be so. We are vaguely aware of the limitations of his knowledge. We know that he has to guess first what is the matter with us, and next what will do us good, and, that though there are facts his acquaintance with which help him to guess right, many theories that regulate his professional action are still hypothetical and may or may not be correct. We know that he has discovered that many of the methods his father used were unwise and deleterious, and that the doses his grandfather gave often hastened the result they were intended to prevent, and hindered what they were designed to induce. We know not only that he is a man, and therefore fallible, but that his professional science, like his father's and grandfather's, is progressive and is still very far from being exact. Nevertheless, when anything ails us, in spite of all we know of his limitations, we fly to him as though he were all wise, and do as nearly what he tells us to as our flesh and our pockets permit, for we believe that, erring and inadequate as he is, he knows more than we do, and that his knowledge is, on the whole, the best that is at our command.

This childlike trust in our physicians is a phenomenon which is creditable to us and to our doctors, and from which we both get benefit. Undoubtedly our physicians do us good; and indeed they ought to, even if they knew less and guessed less fortunately than they do, else were faith a much less potent virtue than it is declared to be. But it is one thing for us to flock of our own accord to the doctors, and quite another thing for those professional gentlemen to hold that we shall come to them and to no one else, and that we may neither be legitimately born nor die legally except with the concurrence of the learned faculty.—*Scribner.*

SKIN GRAFTING BY MACHINERY.—The practice of skin-grafting has become so common of late, and the pain, difficulty and slowness of taking grafts by the manual process of plucking up the skin and clipping it by scissors is so great that Dr. Mixer, of the Massachusetts General Hospital, has set himself to devising machinery to accomplish this purpose. He has succeeded in producing what is pronounced to be a wonderfully successful device, the first use of which is described substantially as follows: The patient had been etherized and had undergone an extensive surgical operation on her breast. The instrument for the removal of skin was applied to the anterior portion of the right thigh, and three strips, about an inch wide by six long, were taken off and transplanted to the exposed surface of the breast. The operation of removing the skin and transplanting it to its new quarters did not occupy more than six minutes. A very few days will suffice to restore the denuded surface of the thigh to its normal condition, leaving few traces of the reparative process, while the portion of breast removed will heal over rapidly by first intention. The thickness of skin removed does not exceed one-sixteenth of an inch. The advantages of the new over the old method of epidermic detachment are obvious. It is expeditious, the sections of shaved cuticle are much larger and of a more uniform thickness than can be obtained by the most dexterous manipulator, and the chances of successful grafting are enhanced by the fact that the skin is transplanted while the cellular elements are in their full vital activity.

HEALTH OF THE STATE.—Reports to the Board of Health from 66 towns and villages, having an aggregate population of 608,945, show a mortality during the month of June of 945, a percentage of 18.60 to the 1000 per annum. Among the causes of deaths and the number of decedents we find the following: Consumption was fatal in 140 cases, being a reduction of 24 since April. Pneumonia was the cause of death in 91, bronchitis in 21, and congestion of the lungs in 11. There were 15 deaths from diarrhoea and dysentery, 8 from cholera infantum, and 34 from other diseases of the stomach and bowels. Diphtheria caused 33 deaths, oroph 13, scarlatina 2, measles 3, and whooping-cough 8. Typho-malarial fever is accredited with 3 deaths, typhoid fever with 20, remittent and intermittent fevers 7, and cerebro spinal fever 3. Cancer caused 24, erysipelas 3, heart diseases 58, alcoholism 8, and all other causes 420.

SCIENCE IN RELATION TO INEBRIETY.—Dr. Shorthouse has been diagnosing the effect of various intoxicating liquors on different parts of the cerebellum when imbibed "not wisely but too well," and the tendency of the result of his investigations is to indicate that inebriety can be reduced to an exact science, so far as the subsequent demonstrations are concerned. Dr. Shorthouse finds that good wine and beer indirectly imbibed have the effect of making a

man fall on his side; whiskey, and especially Irish whiskey, on the face, and older and purer on his back, these disturbances of equilibrium corresponding exactly with those caused by injury to the lateral lobe and to the anterior and posterior parts of the middle lobe of the cerebellum respectively.

POISONOUS DRY GOODS.—The British Consul at Christiania, in Norway, about four months ago forwarded a letter calling the attention of the Foreign Office to the fact that, owing to the English printed fabrics containing arsenic, there had been a great decline in the quantity of such goods imported into Norway, and the British printed cloths were getting a bad reputation in consequence of their containing such a large excess of arsenic. This letter was forwarded to the Manchester Chamber of Commerce, which procured samples of the goods in question, and they were handed over to Mr. Ivan Levinstein, who had the samples examined, and they were found to contain arsenic in large quantities.

CHANCES IN MEDICINE.—A doctor says that 75 out of every 100 persons who fall into a physician's hands would get well without any help, and the majority of the remaining 25 are past all human aid and the physician gets the blame for not saving their lives.

USEFUL INFORMATION.

A PERFECTLY BLACK PAINT for brass tubes is made as follows: Take two grains of lampblack, put into any smooth, shallow dish, such as a saucer or small butter plate; add a little gold size, and thoroughly mix the two together. Just enough gold size should be used to hold the lampblack together. About three drops of such size as may be had by dipping the point of a leadpencil about half an inch into the gold size will be found right for the above quantity of lampblack. It should be added a drop at a time, however. After the lampblack and size are thoroughly mixed and worked, add 24 drops of turpentine, and again mix and work. It is then ready for use. Apply it thin with a camel's hair brush, and when it is thoroughly dry the articles will have as fine a dead black as they did when they came from the optician's hands.

MOSQUITOES.—The bill of a mosquito is a complex instrument. It has a blunt fork at the head, and is apparently grooved. Working through the groove, and projecting from the angle of the fork, is a lance of perfect form, sharpened with a fine bevel. Beside it the most perfect lance looks like a hand-saw. On either side of the lance two saws are arranged, with the points fine and sharp, and the teeth well defined and keen. The backs of these saws play against the lance. When the mosquito lights, with his peculiar hum, it thrusts its keen lance, and then enlarges the aperture with the two saws, which play beside the lance until the forked bill, with its capillary arrangement for pumping blood can be inserted. The sawing process is what grates upon the nerve of the victim, and causes him to strike wildly at the sawyer.

POSTAGE STAMPS AT LETTER BOXES.—The English Postmaster-General has given permission for an experiment to determine whether postage stamps can be supplied to the public by means of an automatic machine attached to the ordinary pillar boxes. The machine to be used is about 18 inches high and a few inches square, and it can be attached to a pillar box without difficulty. A person desiring to purchase a penny postage stamp drops a penny in the slot at the front of the machine, and a white envelope comes out at the back containing a memorandum hook with a penny postage stamp in a small slit in the cover. Such a device would be the most useful to which the "slot machine" has yet been applied.

TO CLEANSE DEAD GOLD SURFACES, dissolve 80 grammes chloride of lime, 80 grammes double carbonate of potash, and 20 grammes common salt in about 3 litres of distilled water, and set the mixture aside in bottles tightly corked. Place the article to be cleaned in a deep bowl, pour the cleansing fluid upon it until it is entirely covered, and let it soak for some time, heating it if the article is exceptionally soiled and tarnished. Wash, rinse in alcohol and dry in sawdust; it will look like new gold. The cleansing fluid must be thrown away after the operation, as it will have lost its efficacy. Javelle water produces the same effect, but it costs at least eight times as much as the preparation described.

ANOTHER LEATHER SUBSTITUTE.—The scarcity of leather is causing inventors to seek for substitutes for that important material. The latest in this direction is reported for a German inventor who is said to have devised a new substitute for leather in many of its uses. This material consists of panels of wood with wire netting between, the whole being glued together under heavy pressure. The sheets thus made are said to be very tough and pliable, and suited for making trunks and other uses that require strength.

DOVETAILED BRICKS.—Gunga Ram, executive engineer, Lahore, says *Invention*, has in-

vented a new and cheap method for constructing walls and other circular brick work, for which he has taken out a patent. The secret of the invention lies in the use of specially molded dovetailed bricks with which no mortar is required, and the bricks can easily be fitted and locked by unskilled labor. The walls would be both cheaper and stronger than those built in the ordinary way.

SHOP NOTES.

System a Necessity.

The most celebrated but not always the most extensive machine and engine works are those where a correct system is adopted and enforced through all the minor departments of the business. Messrs. Whitworth, the celebrated machine tool makers of Manchester, England, and the Brown & Sharpe Manufacturing Company of Providence, R. I., are noted for their rigid system in the manipulation of their work, and they set a good example in this respect to many other proprietors of shops in which large sums of money are continually lost from the entire want of system, order and good regulations.

System in manufacturing consists, not in having small, cramped-up, badly ventilated, dirty workshops; not in hiring "cheap help"; not in using castings and forgings which are slightly defective, rough and of doubtful material, because they come half a cent per pound cheaper; not in placing uneducated foremen over a gang of men who think they know, and often do know, more than their "boss"; not in hurrying work off half finished, half daubed over with paint, half packed; not in working tools out of line or out of true; not in giving orders to the men in place of the superintendent, foreman or head of a department; not in altering patterns without informing the draughtsmen; not in hurrying, fussing, pushing and driving men and machinery until no one knows where he stands or what to do for the best, or how to please, or what to work to, or whose orders to obey. This, and a great deal more, is not system.

The statement of what is not system will facilitate the explanation of what it consists in. The workrooms should be clean, neat and airy, if not large; the shafting and tools kept tight; the wrenches, taps, dies and reamers for shop purposes, marked and arranged in racks and returned there when done with; the benches swept down daily, and a proper provision made for the hands to wash. When a tool is broken or out of order, it should be repaired or replaced immediately. Order, cleanliness and neatness should be instilled so thoroughly that men "get used to it," and take pride in having things look neat and systematic. Attention should be paid to certain standard sizes, standard gages, standard diameters, lengths and proportions. All orders should come from the proper source, and be given to the heads of each department.

First-class help is always the best, cheapest and most reliable, and that help should be paid well and regularly. "Our prices won't admit of this," says one employer. We ask, do you turn out first-class machinery, which will wear and run well? If you do, we answer that you can always employ good help and get good prices.

Introduce system, we say, to all machine builders. It matters not what peculiarities there may be in the particular one you may adopt, but, at any rate, have system, not in theory but in practice; system which the hands dare not encroach on; rules and regulations which to break is to be highly censured. Introduce plan, method and quiet, firm, orders, which the employees will respect, and for which they will work harder; and at the end of the year, there will be so much to add to your profits, for you have a well regulated and systematic machine shop.—*American Engineer.*

DRIVING PULLEYS ON TO AN ARBOR.—A mechanic who has been driving pulleys on to an arbor wonders what makes them catch once in a while and ruck up. The two metals seem to unite, and when the arbor is finally forced out of the pulley, if it is ever forced out at all, it leaves a bunch of the two metals so hard that a file won't have any impression on it. Now, what causes the metal to harden? The trouble is that these little hard spots are in the metal to start with, and are not made so by compression. They cause the boring tool to stand off while it is passing over them, and when the arbor is driven, they are the first to take the strain, and soon gather up in front of them quite a jam to resist the further driving of the mandrel. It does not take much of a particle to make a disturbance between the surfaces when there are tool-marks and imperfections to contend with. This is better seen in removing shrunk fits; the least hard spot will gather quite a bunch in front of it. The beauty of reamed holes is that the force of the arbor is spread over a surface large enough to do all the driving that is required by friction alone, without causing abrasion on any portion of the surface. In grinding plug gauges and trying them on their rings, great care must be taken to keep them well oiled, or they will take a notion to "seize," and when they do, the more it is tried to separate them, the firmer they seem to hold.—*Ex.*

It is poor management to see one machine for half a dozen different things.

ELECTRICITY.

COAL MINING BY ELECTRICITY.—The *Free Press*, published at Nanaimo, B. C., tells us follows of how coal mining is done at the Union mines, Vancouver Island, by electricity: "A representative called on A. Dick, Government Inspector of coal mines, on his late return from an official visit to the Union Colliery at Comox. Mr. Dick then gave a description of the electric machine—the first of the kind he had seen—as wonderful and doing its work with the utmost ease and the precision of clockwork. He timed the machine while at work and found that it 'mined' 6 feet by 39 inches and 4 inches deep in five minutes. It also took five minutes from the time of finishing out until it commenced work on the next. To move it from one stall to another takes about half an hour. Mr. Dick expressed the opinion that it will greatly facilitate the mining of coal, and also that the coal will come out in a more merchantable condition. In fact Mr. Little, manager, and Mr. Russell, overseer, said the refuse from the machine was not half that by the ordinary mode of mining. D. N. Osyos, electrician of the Jeffrey Company, of Columbus, Ohio, is at present at Union placing the machinery in order and instructing the operators. Mr. John Ead is in charge of the cutting machine, having one helper, who with an engineer in charge of the dynamo, is the entire working force. The steam is supplied from the colliery boilers, Mr. Osyos says that in the long wall system of coal mining the machine can do a much greater percentage of work than in the small stall system. The machine simply does the under-mining, then the miner has to come along, drill the holes, fire the shots, and load away the coal."

AN ELECTRIC ELEVATOR.—The American Elevator Company, 15 Cortland Street, New York, is manufacturing an elevator which is run by an electric apparatus placed in the top of the elevator shaft, and which occupies a space of only four by six feet and four feet high. The machine is very simple, of comparative light weight, and as it produces no appreciable vibration, there is no obstacle to placing it aloft instead of at the bottom of the shaft, by which arrangement the pull on the car is always in a vertical line. The armature shaft of the motor is coupled direct to the worm shaft and this coupling is also a brake wheel, to which the brake is applied automatically when the current is cut off, and thus not only serves the purpose of overcoming the momentum of the armature when stopping, but also serves to hold the car stationary, if through accident at the gearing station or from any other cause, the current should be cut off. The operating rope starts, reverses or stops the car at the will of the operator. There is none of the noise and disagreeable jerking of the car which makes the belt machines and spur gear machines so objectionable. The motors are of a slow speed type, made especially for elevator service. As the motor runs only when the elevator is in actual motion, no current is used during the time the elevator is standing, and if any one will take the trouble to compute the time an average elevator is standing still, they will be surprised to find how much it exceeds the time in which the current is used. Another important point is the fact that while you have here a motor capable of developing five, ten, fifteen or twenty horse power, it actually develops only the power required at the moment.

SAFETY OF THE ELECTRIC CURRENT.—Gradually the press of the country is arriving at the conclusion that "the deadly electric current" is not so deadly after all, and that, as the *Chicago News* expressed it in a recent editorial, "a very large percentage of the accidents and deaths attributed to electricity have been due to sheer carelessness or wanton horseplay." This is a gratifying indication that the public generally is ceasing to regard electricity with that panicky fear which has characterized it in New York and some other large cities where accidents due to electric light wires have occurred. Like any other powerful manifestation of energy, electricity should always be treated with an intelligent appreciation of its tremendous latent possibilities, either for good or evil; but when this feeling is replaced by a blind and unreasoning terror, the community in which such a panic prevails is simply placing obstacles in the path of progress upon which it itself should travel.

PHOSPHORUS BY ELECTRICITY.—Phosphorus is now manufactured at Wolverhampton, England, by the aid of electricity. The process consists in decomposing the mixture of phosphoric acid, or acid phosphates and carbon, by the heat of an electric arc imbedded in the mass, and the inventors urge that the local application of heat in this form is more economical than the heating of large retorts containing the mixture in the ordinary process.

ELECTRO PNEUMATIC TUBES.—Experiments are fast bringing to a practical conclusion the proposition that mail matter may be forwarded at a speed of 120 miles an hour for short distances, and by a system of quick transfer stations, a speed of 100 miles an hour may be kept up indefinitely. The establishment of an experimental line between New York and Philadelphia seems to be an ascertained fact.

SCIENTIFIC PRESS PATENT AGENCY.

DEWEY & CO., PATENT SOLICITORS.
A. T. DEWEY. W. B. EWER. G. H. STRONG.

SAN FRANCISCO:

Saturday, June 27, 1891.

TABLE OF CONTENTS.

EDITORIALS.—Grating Screens for Coal; Mines on Odd Sections, 401. Passing Events; Close of the Volume; California's Mineral Resources; A Mineral Exhibit; Pacific Coast Patents; Timber on Mineral Land, 403.

ILLUSTRATIONS.—Grating Screens for Coal, 401. Machinery for Handling Gravel, 409. MISCELLANEOUS.—A Lixiviation Plant; Delicate Heat Measure; The Malay Gold Mines; New Incorporation; Machinery for Handling Gravel, 402. MECHANICAL PROGRESS.—Phenomenal Friction; Why Does Solid Iron float on Melted Iron? Where the Iron Grows; Checked Combustion; Iron and Steel Forging; A Foundry Hint; Invention; Miscellaneous, 406.

SCIENTIFIC PROGRESS.—A Cosmical Telephone; Agricultural Science—The Origin and Uses of Humus; Why Snow is White; Light and Heat; A Curious Instrument; Age of the Glacial Period; Submarine Discovery; Artificial Malachite; A New Sewing Machine; The Future of Chemistry; The Barometer and Earthquake; The Earliest Weather Record; Miscellaneous, 406.

GOOD HEALTH.—The Physician as a Despot; Skin Grating by Machinery; Health of the State; Science in Relation to Inebriety; Poisonous Dry Goods; Chances in Medicine, 407.

USEFUL INFORMATION.—A Perfectly Black Paint; Mosquitoes; Postage Stamps at Letter Boxes; To Cleanse Dead Gold Surfaces; Another Leather Substitute; Dismantled Bricks, 407.

SHORT NOTES.—System a Necessity; Driving Pulleys on to an Arbor; Miscellaneous, 407.

ELECTRICITY.—Coal Mining by Electricity; An Electric Elevator; Safety of the Electric Current; Phosphorus by Electricity; Electro Pneumatic Tubes, 407.

MINING SUMMARY.—From the Various Counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 404.

MINING STOCK MARKET.—also in the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, etc., 412.

MARKET REPORTS.—Eastern and Local Metal Markets; Coal and Coke, etc., 412.

Business Announcements.

[NEW THIS ISSUE.]

Mining Machinery—Pacific Iron Works.
Quartz Ledge and Ranch—Levy Brown.
Notice to Intruders—The Cummings Rock Drill Co.
Dividend Notice—The San Francisco Savings Union.
Dividend Notice—The German Savings and Loan Society.

Passing Events.

This is the last number of Volume LXII of the MINING AND SCIENTIFIC PRESS, and it is proper to suggest that this is a good time for the renewal of subscriptions and the commencement of new ones.

This week a number of molders arrive from the East to work in the local foundries, and it is thought that this will make a very material change in affairs here, greatly strengthening the hands of the California foundrymen. The new members of the Brotherhood of Machinery Molders and understand the situation of the strike here.

The Cabinet is this week considering the subject of silver coinage to determine whether the coinage of standard silver dollars shall continue after July 1st. The prevailing sentiment with leading Treasury officials is, that the proposition will be adopted. New York bankers oppose further coinage.

Another California mine—the Gover in Amador county—has started its pumping works with electricity and water power in place of steam. The use of electricity for power in mining operations is gradually extending.

DENVER is to have a "Mining Congress" next September.

We Shall Be Obligated.

The publishers of the PRESS would consider it a favor for subscribers to renew their subscriptions during the coming month. Many of those whose subscriptions have expired, or are about to, would probably not inconvenience themselves but would oblige us by promptness in sending in the money. A settlement of this kind from several hundred readers is of material assistance on occasion though the amount may be small from each. The price of the PRESS is sufficiently small so it should be little trouble for our subscribers to answer this appeal.

Portland Agency.

Mr. Arthur M. Mitchell will act as agent and correspondent for this office for the present, at Portland, Oregon. He has good recommendations and will use his best efforts in behalf of the readers and patrons of the paper in our North Pacific States. Whatever assistance our friends can render him in his efforts for us will be duly appreciated.

Close of the Volume.

Volume LXII of the MINING AND SCIENTIFIC PRESS ends with the number issued this week. The PRESS is the pioneer of all the mining journals of the United States, having appeared weekly since May, 1860.

The volume contains a pretty complete history of the mining industry of the country—a history that not only includes that of camps and districts, but one of the various metallurgical processes, mechanical appliances of mining, the successes and failures of each branch, and the existing condition of the business.

The experience of all those years enables the proprietors and editors to obtain and prepare suitably the information most desired by the mining community and most to its advantage.

These appliances, both for mining and metallurgy, are described and illustrated as they come to the front, enabling the miner, millman and smelter to see the advances in his particular branch, and to keep abreast of the times. Such new processes as are being tried with any show of success are described in these columns in a manner to be intelligible to all. Our numerous correspondents also gather a mass of miscellaneous information concerning different localities as may interest the mining reader. The current news of all the districts and camps is given weekly in a condensed form so as to post people generally on the progress in various mines. The PRESS is, perhaps, equally commendable for what it has excluded from its columns, viz., puff of wild cat mining schemes.

The last page of the PRESS this week contains the index of the volume, from a glance at which may be seen the varied scope of the contents of the paper. The subjects treated, while more or less technical, are enlivened in a popular form intelligible to all. The progress of the country in its mechanical and scientific branches is chronicled in these columns; and such things as may be of value in the everyday life of the industrial and progressive classes are sought for and published from week to week.

The PRESS is a necessity to the mining and industrial public of the Pacific Coast. Those who are already among its readers should further assist it by calling the attention of others to the paper. We shall naturally be glad to increase our list of subscribers, that still further improvement may be made.

California's Mineral Resources.

A call has been issued for a State Immigration Convention to be held in this city August 24th, and delegates are to be invited from all the counties. The intention is to promote in some suitable manner the work of inducing desirable immigration to this State.

Most of the "immigration literature" which has thus far appeared deals entirely with the agricultural and horticultural possibilities of certain tracts of land. The mining industry of the State seems to have been entirely ignored. Now while the counties are selecting their delegates to this proposed convention it will be well for those who have mining ground, and few have not, to impress upon their representatives the fact that attention should be called to the mining fields. There is plenty of land in all the agricultural States, but few if any have lands that can be devoted to both agriculture and mining as is the case in California.

Our mineral field is varied and large. Not

only is California the greatest producer of gold of any of the States, but she has maintained that same position since 1849. The State also yields silver, tin, copper, quicksilver, iron, borax, coal, gypsum, manganese, asphaltum, petroleum, mica, asbestos, salt, bituminous rock, chrome, marble, building stones, graphite, and a dozen other mineral products, many of them in large quantities. It scarcely seems possible that the existence and presence of all these things should be ignored in pamphlets and papers supposed to herald the resources of the State. Yet such is the fact. They are scarcely mentioned. So many pages are required to tell about the oranges, grapes and other fruits that nothing is said of the mines or mining industry.

The representatives of the mining counties should see to it, in the coming convention, that the mineral resources receive a fair share of attention. They have not got them elsewhere as varied as we have, and they should present a powerful attraction for people who are looking for a home in a land of plenty.

A Mineral Exhibit.

The first of the great World's Fairs was that of the Crystal Palace, London, in 1851, and it was there that the first practical demonstration was made of the value of a mineralogical collection as an object lesson to the general public. "Few among the great crowds at that Industrial Exhibition who swept by the series of iron ores brought together from all parts of Great Britain by Mr. Blackwell could have prophesied that the collection of half a dozen of these somber stones would give rise within a few months to an active industry which bids fair to develop a new phase in the gigantic phenomenon of the British iron trade. An example, this, of the mutual dependence and assistance of these intercolony where geological reasoning had to point out the tract in which a given formation was to be found, mineralogical observation to discover the actual deposit, and chemical analysis to determine the value of the ore."

This quotation is from the introductory lecture to the course of mineralogy and mining in the English Government School of Mines, delivered in 1852 by the late Warrington W. Smyth, the famous geologist. The half-dozen specimens alluded to were taken by Melville Attwood (now of this city) from the newly discovered iron ore beds in the Oolite formation, he having been appointed to assist Mr. Blackwell in making a collection of North of England iron ores for the Exposition of 1851.

Prof. C. Le Neve Foster, who took the place at the head of the School of Mines left vacant by the death of Sir Warrington Smyth, in his introductory lecture, Jan. 19, 1891, speaks of the Cleveland iron district as now producing between five and six million tons annually. This is the district from which the half-dozen specimens were shown in 1851.

No better illustration than this could be given of the importance of a collection of minerals publicly exhibited. The specimens in question attracted the attention of capitalists, with the result that this immense and profitable field was developed and has continued to produce ever since.

A proper representation of the mineral possibilities of this State, before the hundreds of thousands of visitors at the World's Fair at Chicago, is sure to redound to the benefit of California. As we have suggested in a previous number of the PRESS, such collections have already been made by State officials, and more could be added, so that a magnificent display could be made. It is only to be hoped that when steps are inaugurated, we will have no quarrels as to the manner, but unite in assisting to make the mining exhibit of California a success.

The new "Factory Law" in England prohibits children under 11 years of age from working in factories. This will affect from 150,000 to 200,000 children now employed in the factory districts as half-timers.

The new Mills' building in this city will have its front for two stories made of Inyo Co. marble. The stair steps and floor tiling will be of the same material.

The California buildings at the World's Fair will occupy about two acres on one of the best sites in the grounds.

Pacific Coast Patents.

There were 19 patents granted, in the week ending June 16th, to inventors on the Pacific Coast, and of this number, 14 were obtained through the MINING AND SCIENTIFIC PRESS Patent Agency. This is the oldest established agency on this coast, and it is but natural that it should obtain and keep the bulk of the business. There is a substantial advantage in an inventor being able to explain in person to the specification writer, instead of writing letters, as is the case where Eastern agents are employed. Moreover, the inventor can read and revise his completed papers and inspect the finished drawings, so that the case can be forwarded to the Department, and embody all the inventor's ideas, without errors or omissions; and even where it is necessary to carry on the business by correspondence, it is not necessary to lose much time in the interchange of letters, and the coast inventor may revise his specification before it is sent on. He also knows where to find his solicitor if anything ever seems to go wrong, or personal explanations finally prove necessary.

On the last page of this week's PRESS is an index of all patents granted to Pacific Coast inventors for the half year ending this month. Of the large number of patents there enumerated, the largest proportion were obtained through the MINING AND SCIENTIFIC PRESS Patent Agency and most of them have been described in these columns.

Having had an experience of over a quarter of a century in the business of obtaining patents, the proprietors of this agency are enabled to save much trouble to inventors and obtain good results. They can also insure promptness and accuracy. The agency has the best technical library on the coast, with full and complete official files, all of which is available to inventors. Under these circumstances it is no wonder that Pacific Coast inventors continue to give the bulk of patent office business to the MINING AND SCIENTIFIC PRESS Patent Agency.

Timber on Mineral Land.

On May 16th (page 306), we published in the PRESS the circular letter of Commissioner Carter of the General Land Office, giving the instructions which govern in carrying into effect the sections of the General Land Act of March 3, 1891, relating to the cutting of timber on public lands. The sections only apply to Colorado, Montana, Idaho, North Dakota, Wyoming and Nevada, the Territory of Utah and District of Alaska. These instructions show that settlers, miners, farmers and other residents who have not a sufficient supply of timber on their own claims for firewood, fencing or building, or for necessary use in developing the mineral or other resources of their lands, are permitted to procure timber from the public lands for these purposes, but not for sale or use on other lands or by other persons. The law specially provides that sawmill owners, lumber-dealers and others who get timber taken from public lands are as guilty of trespass as those who actually cut it.

Permits may be obtained from the Secretary of the Interior to cut timber on the public lands for purposes of merchandise, under certain conditions prescribed in the Act.

A certain class of poor and ignorant wood-choppers, and also wood purchasers, are apt to get into trouble at once if this law is not complied with. Permits must be taken out at once if they are cutting timber on public lands and selling it. If a miner is using it on his own claim he needs no permit; but the Act of June 3, 1873, relative to cutting timber to sell, on the public lands, is still in force. All cases of cutting for sale in violation of the provisions of that Act in the Act of March 3, 1891, will be prosecuted.

The new Act of March 3, 1891 took effect on the day of its approval, and is, of course, now in force. The fact that a wood-cutter did not know of the new law will do him no good in case of prosecution by the Government. The regulations will be enforced immediately.

C. J. EAMES of Pittsburgh offers to put up an iron and steel plant of 100 tons daily capacity in San Diego, for a subsidy of \$200,000 in mines and lands.

WORK has been resumed at the Black Diamond mines, Wash., this week, the miners having come to the terms of the company.

SECTION SHOWING SEPARATING MACHINE AND SLUICE-BOXES.

AUTOMATIC ELEVATOR AND PUDDLING MACHINE FOR AURIFEROUS GRAVEL.—See Pages 402 and 403.

LEAD AND SILVER.—A number of gentlemen interested in the importation of lead ore have informed the Treasury Department of a proposition to resuscitate the smelting scheme at Vanocover, B. C., and they desire to know where the most available ores are found within the limits of the United States and near the

northwestern bonndary, and if the same may be exported and the resulting hullion brought back to this country free of dnty. Asstant Secorstory Spandling, who has been giving the matter attention, says if the resulting hullion should turn out to be silver it could come in free, but if lead a dnty must be paid.

THE ANACONDA.—L. C. Stump, agent of the Hearst estate, which is known to have an interest in the Anaconda copper mine, admits that the property has been bonded to an English corporation under the name of the Exploration Co., and that the bond will expire October 1, 1891. He denies that any sale has

yet been effected. Mr. Hagglin, the principal owner, also denies the reported sale.

R. W. GORRILL has obtained the contract for the new dam across the Tuolumne river about two miles from La Grange. The work will cost about \$350,000.

TECHNOLOGY OF ANIMAL, VEGETABLE,
AND MINERAL**FATS AND OILS AND LUBRICANTS**
—AND—
SOAP AND CANDLES.

BRANNT.—A Practical Treatise on Animal and Vegetable Fats and Oils; comprising both Fixed and Volatile Oil, their Physical and Chemical Properties and Uses. The manner of Extracting and Refining them, and Practical Rules for Testing them, as well as the Manufacture of Artificial Butter, Lubricants, including Mineral Lubricating Oils, etc., and on Ookerite. Edited from the German and other sources by W. T. Brant. 240 engravings, 730 pages, Svo. Price.....\$7.50

BRANNT.—A Practical Treatise on the Manufacture of Soap and Candles; comprising the Chemistry, the Raw Materials, the Machinery and Utensils, and Various Processes of Manufacture, including a great variety of formulae. Edited chiefly from the German by W. T. Brant. 163 engravings, 677 pages, Svo. Price.....\$7.50

CREW.—A Practical Treatise on Petroleum; comprising its Origin, Geology, Geographical Distribution, History, Chemistry, Mining, Technology, Uses and Transportation; together with a description of Gas Wells, the Application of Gas as Fuel, etc. By Benj. J. Crew. With an Appendix on the Oil Regions and the Geology of Natural Gas in Pennsylvania and New York. By Chas. A. Ashburner. 70 engravings and two plates, 503 pages, Svo. Price.....\$5.00

CRISTIANI.—A Technical Treatise on Soap and Candles. By K. S. Cristiani. 176 engravings, 581 pages, Svo. Price.....\$10.00

Illustrated circulars, giving the full tables of contents of all the above works, sent free to any one who will apply.

The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

Our new revised Descriptive Catalogue of Practical and Scientific Books, 87 pages, Svo, and our other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.

QUARTZ SCREENS
A specialty. Round, slot or hurred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and absolutely water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated. Price, \$2 each, or the entire instrument finished in gold plate, \$5.
N. W. MOODEY, Fresno, Cal.

THE AIR BRUSH

Applies liquid pigment by a jet of air. Highest awards Franklin and American Institutes as a legitimate art tool. Successfully used by large numbers of the best crayon, ink and water-color portrait artists, and by technical draughtsmen. Saves 75 per cent of time in shading.
Descriptive pamphlet sent free. It points out one way to earn a living. Address: AIR BRUSH MFG CO., 9 Nassau Street, Rockford, Illinois.

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as
The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safe in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blast ing Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

GOLD MINES

—AND—
STOCK IN MINES FOR SALE.

Dividend-paying Mines from \$150,000 up.
Undeveloped Mines from \$10,000 up.
Undeveloped Mines on Bond.
Stock in Dividend-paying Mines from \$1 up
Stock in Undeveloped Mines now being opened from 25 cents up.

All situated in the GRASS VALLEY MINING DISTRICT, the Oldest Quartz Mining District on the Pacific Coast, and the Richest and most Permanent in the World. The mines of this district are practically inexhaustible, as nearly half a century of constant working is proof. Grass Valley has the deepest regular dividend-paying gold mines in the world, and the end is not yet, for these same mines are as rich to-day as at any time during their history.

Gold mining, especially in Grass Valley, when under honest and scientific management, is one of the safest and most profitable of all American industries. It is a business that will return annually a profit of from 100 to 300 per cent on the investment. Mining is a science acquired only by years of study, combined with practical experience. Therefore, failure is the rule whenever the management is ignorant and unscientific.

The undersigned is a practical scientific and successful miner, has made mining a life study and vocation, is honest and trustworthy, and will not, under any circumstances, recommend or deal in any but valuable paying property and properties that will develop dividend-paying.

No Wildcat Mines; no Sharp Practice; no reasonable chance for loss; Honesty and Square Dealing Guaranteed. Correspondence solicited.

Full particulars by applying to
S. B. FOWLER, Supt. Hartley Mine,
Grass Valley, Nevada Co., California.

THE RUSSELL PROCESS.

For information concerning this process for the reduction of Ores containing precious metals, and terms of license, apply to

THE RUSSELL PROCESS CO.,
Park City, Utah.

ELECTRIC BLASTING.

VICTOR ELECTRIC PLATINUM FUSES.
Superior to all others for exploding any make of dynamite or blasting powder. Each fuse folded separately and packed in neat paper boxes of 50 each. All tested and warranted. Single and double strength, with any length of wires.

VICTOR BLASTING MACHINE. Made in two sizes. No. 2 fires 20 to 30 holes. No. 1 fires 5 to 8 holes. Adapted for prospecting, stump blasting, quarry and general railroad work.

"PULL UP" BLASTING MACHINE. - The strongest and most powerful machine ever made for Electric Blasting. No. 4 size fires 70 holes. No. 3 size fires 40 holes. Are especially adapted for submarine blasting on large mining work.

Standard Electric Fuse and Blast Tester, Wire Reels, new design, Lending and Connecting Wire.

MANUFACTURED ONLY BY
JAMES MACBETH & COMPANY.
125 Maiden Lane, New York City.

JOSHUA HENDY MACHINE WORKS,

Nos. 39 to 51 FREMONT STREET, SAN FRANCISCO, CAL.

"HENDY" IMPROVED "CHALLENGE" ORE FEEDER.

The best form of Feeder ever devised, and pronounced by reputable mining men to be far superior to any form of "Roller" Feeder manufactured. We refer to the following gentlemen who have furnished us with testimonial letters to the above effect, which can be seen at our office, viz:

N. W. CROCKER, Supt. Bunker Hill Gold Mining Co., Amador City, Cal.
W. G. ROBERTS, Greenwood, El Dorado Co., Cal.

D. O. WICKHAM, Taylor Mine, Greenwood, Cal.
J. R. TREGLOAN, Supt. South Spring Hill Gold Mining Co., Amador City, Cal.

WE ARE MANUFACTURERS OF THE

"CHALLENGE", "STANFORD", "TULLOCK", & "ROLLER" FEEDERS,
And will furnish descriptive Catalogues and quote prices upon application.

THE BLASDEL CONCENTRATING BELT COMPANY.

We have now made arrangements to have our new Concentrating Belt manufactured in San Francisco; we can therefore fill all orders on short notice. The length and width of these belts are the same as is used on the Frue or Triumph Concentrating Machines, but can be made of any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksiver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

Adamantine Shoes and Dies—AND—**CHROME CAST STEEL**

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by **CHROME STEEL WORKS, Brooklyn, N. Y.**

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.

121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS, Varying from the fraction of 1 up to 15 and 20-horse power, unequaled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs;" for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if need be. Circulars and testimonial letters furnished on application.

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont Street, San Francisco, Cal.

(PATENTED.)
Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

Original Empire Mill and Mining Company,
Principal Office, 401 California St., cor. Sansome, S. F.
Location of Works, Grass Valley, Nevada Co., Cal.
GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1885.
JOSHUA HENDY MACHINE WORKS, 39 to 51 Fremont St., S. F., Cal.:
GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.
At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrator is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID MCKAY, Jr.
[Signed] Supt North Star and Original Empire Mining Co.
N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.
